RP301

INDEX

- ABBEY House Museum, Kirkcaldy · Folk Gallery to be opened by Dr. F. Sharywood Taylor, 1217
- Abbot, Dr. C. G.: Forecasting Weather from Solar Radiation, 880
- Abbreviation of Bacterial Generic Names, 663
- Abel, A. L.: Weed Control, 149
- Abelson, Dr. Denis (Baron, Dr. D. N., and): Cortisone and Hydrocortisone in Cerebrospinal Fluid, 174
- Abercrombie, Michael: Recent Advances in Animal Morphogenesis, 519
- Abercrombie, Michael, and others (edited by): New Biology, No. 16, review by T. H. Hawkins, 1109
- Aberrombie, A. New Method of Transporting Optical Images without (Prof. A. C. S. van Heel), 39
- Ablett Prize for 1953 of the Iron and Steel Institute awarded to F. Starkey, 852
- Abnormal Accumulation of 3-Hydroxykynurenine in the Mutant 'Aka-Aka' of Silkworm (Katsush Makino, Hitoshi Takahashi, Kiyoo Setoh and Kaoru Inagami), 586
- Abnormalities of Stored Seed (B. J. Harrison and Dr. J. McLeish), 593
- 80 Groups in Blood Platelets (Dr. J. Gurevitch and D. Neikun), 356
- Aborigines (Australian): Geological Evidence in Western Victoria relative to the Antiquity of the (E. D. Gill), 1124
- Abortion (Habitual): A Remarkable Family with the Rare Human Isoantibody Anti-Ty in Four Siblings—Anti-Ty and (Shohei Iseki, Shinju Masaki and Dr. Philip Levine), 1193
- Abraham, Dr. E. P., and others: Structure of Bacitracin A, 536
- Abraham, H. J. M.: Annual Fluctuations in Quartz Clock Error and Frequency Drift, 73
- Absenteeism of Workers in Small and Large Organizations, 383
- Absolute Configuration by Laue Photographs: Determination of (Dr. H. Judith Greenville-Wells and Prof. Kathleen Lonsdale), 1145
- Absolute Configuration of Cholesterol (Dr. J. W. Cornforth, Irene Youhtsky and Dr. G. Popjko), 536
- Absorption: Human Vascular Purple and (Dr. M. H. Pirrenne), 215
- Absorption: Gas (Institution of Chemical Engineers Symposium on), 292, 1028
- Absorption (Infra-red): Quantitative Evaluation of Paper Chromatograms by (Dr. J. D. S. Goulden), 646
- Absorption of Optical Antipodes by Proteins: Selective (W. Bradley and Prof. R. A. Brindley), 312
- Absorption of Phosphorus-32 from the Rabbit Vagina under various Hormonal Conditions (Dr. Lars Ph. Bengtsson), 954
- Abstract Set Theory (Prof. Abraham A. Fraenkel), review by Dr. R. G. Cooley, 967
- Academic Freedom—Its World-wide Significance, 553
- Academic Freedom and Security Problems, 695
- Academic Visitors to the United Kingdom (Association of Universities of the British Commonwealth), 526
- Acceleration of Partially Stripped Heavy Ions (Dr. Robert S. Livingston), 54
- Accelerators (High-Energy), and Cosmic Rays (Physical Society Symposium on), 292
- Accelerators (High-Energy), Cosmic Rays and Electrical Processes in Cases—Dublin Meeting of the Physical Society (Dr. T. E. Nevill), 1127
- Acclimatization in Insects: Temperature (E. H. Colbourn), 582
- Acclimatization and the Thermal Death Point in Insects (Dr. Kenneth Mellanby), 582
- Accountability: Nationalized Industries and (H. Crookshank), 382
- Accretion of Matter by Stars: The Rate of (Prof. W. H. McCrea), 19
- Accretionary Origin of Comets, review by Prof. W. M. H. Greenlee, 415
- Accumulation of 3-Hydroxykynurenine in the Mutant 'Aka-Aka' of Silkworm: Abnormal (Katsush Makino, Hitoshi Takahashi, Kiyoo Setoh and Kaoru Inagami), 586
- Acetyl Phosphate: Formation of, by the Action of X-Rays on Monoethyl Phosphoric Acid in Aqueous Solution (Dr. George Scholes and Dr. Joseph Weiss), 267
- Acetylation of isoNicotinic Hydrazide: Biological (Dr. Katsush Makino, Takao Kinoshita and Toshiyoshi Itoh), 36
- Acetylcholine and 5-Hydroxytryptamine: Marine Invertebrate Preparations useful in the Bioassay of (Dr. John H. Welsh), 955
- Acetylene (Dissolved): Use of, in Liquid Scintillation Counters for the Measurement of Carbon-14 of Low Specific Activity (B. N. Audric and J. V. P. Long), 992
- Achievement of Refugee Scholars: The Rescue and (Norman Benwich), review by Dr. H. E. Wimperis, 1201
- Achromobacter: Denitrification of Nitrates by a Species of (Jean B. Youst), 826
- Ackogenic Carotenoid in a Bathypelagic Nemertean Worm (Prof. Denis L. Fox), 583
- Acids: Cytological Fixation of Mitochondria by (Dr. W. G. Bruce Casselman and Miss Barbara M. Jordan), 1095
- Acids (Organic): Inhibition of Enzymes by the Fluorides of (Dr. D. K. Myers and A. Kemp, Jun.), 33
- Acids (Volatiles): Separation of, by Paper Chromatography (H. S. Burton), 127
- Acids of Ox Pernephric Fat: Volatile (R. P. Hansen and A. G. Minnes), 1093
- Acoustics (Modern): Principles of (Prof. George W. Swenson, Jr.), review by T. M. Yarrowood, 932
- Acoustics of Orthoptera (Institut National de la Recherche Agronomique Symposium on), 244, 1219
- Acta Hydrophysica, a New Journal of Marine Physics, 860
- Acta Physiologica Latinoamericana, Vol. 3, Nos. 2 y 3, Numero de homenaje al Prof. Alejandro Lipshutz, 902
- Action of Ionizing Radiations on Water: Chemical Primary Processes in the—Evidence from Experiments with Heavy Water (Patrick Kelly, Dr. Tyson Rigg and Dr. Joseph Weiss), 1130
- Action of X-Rays on Monoethyl Phosphoric Acid in Aqueous Solution: Formation of Acetyl Phosphate by the (Dr. George Scholes and Dr. Joseph Weiss), 267
- Activity: Diffusion of Alkaline Phosphatase to Characteristic Intracytoplasmic Sites of (R. Barter), 1233
- Activity of Fungi in Dried Soil (R. G. Atkinson), 337
- Actomyosin: Light Scattering by Very Large Molecules—Application of Transmission Method to (M. L. R. Harkness and A. Wassermann), 167
- Acton Society Trust: Size and Morale, Preliminary Study of Attendance at Work in Large and Small Units, 383
- Adam, Dr. H. M.: Elected a Fellow of the Royal Society of Edinburgh, 474
- Adams, E. T., and others: Some Physical Properties of Metallic Plutonium, 535
- Adaptation: Long-Term, to the Fermentation of Galactose in *Saccharomyces cerevisiae* (David D. Pittman and Prof. Carl C. Lindgren), 408
- Adaptive Changes in Sunflower, *Helianthus annuus* (G. E. Blackman and G. L. Wilson), 766
- A.D.E. Photo-electric Integrator (J. R. Lowe), 1222
- Adenine Carbon-14 in Deoxyribonucleic Acid: Detection of, by Autoradiography (Dr. L. G. Laytha), 587
- Adenosine Triphosphate: Influence of Cation-Exchange Resins on (N. A. Lund, F. S. M. Grylls and J. S. Harrison), 544
- Influence of the Nucleus on Anaerobic Breakdown of (Prof. J. Bracher), 725
- Adhodote vocica: Antitubercular Effect on an Extract of (K. C. Gupta and I. C. Chopra), 1194
- Adjutants, G.: Electrophoretic Separation on Filter Paper of the Soluble Liver-Cell Proteins of the Rat using Borate Buffer, 539
- Adrenal Cortex of the Guinea Pig: Effect of Experimental Tuberculosis on the Distribution of Alkaline Phosphatase in the (Dr. Amiya B. Kar), 210
- Adrenocorticotrophic Hormone: Chromatophore Effect of (Dr. O. Paccanik and M. Zel), 35
- Adsorption: Effect of Surface Diffusion on Rates of (D. Patterson), 1184
- Adsorption of Prosthetic Phosphatase on Ion-exchange Resin (Dr. Hans G. Boman), 447
- Adsorption Columns in the Analysis of Soap and Detergent-stabilized Emulsions: Use of (R. P. Harker, J. M. Heaps and J. L. Horner), 634
- Adult: Effect of Refrigeration of the Pupae of *Microbracon brevicornis* Wesm. on the Pigmentation of the (E. S. Narayanan, G. W. Angalet, B. R. Subba Rao and G. L. D'Souza), 503
- Adult Female Lower Jaw from Makapansgat (Prof. Raymond A. Dart), 286
- Advancing Years: Our (Dr. Trevor H. Howell), review by Mrs. Margaret Hill, 7
- Aeronautical Sciences, Institute of, and others: Celebration of the contribution by engineers to the development of powered flight, 150
- Citation awarded to Dr. W. F. Durand for his services to engineering and aviation, 150
- Aeronautical Society, Royal: Awards, 852
- Aeronautics: Citation for Engineering and, awarded to Dr. W. F. Durand (American Society of Mechanical Engineers, the Institute of Aeronautical Sciences and the Society of Automotive Engineers), 150
- Aesthetics and the Gestalt (Ian Rawlings), review by Dr. Martin Johnson, 230
- Aether Drift Experiment: Proposal for a New (Mrs. H. Littman Furth), 80; (Dr. L. Essen), 734, erratum, 807
- Aether and Electricity: A History of the Theories of (Sir Edmund Whittaker), review by Dr. R. Hagedorn, 838
- Affinity of Sambucanin for Nucleic Acids (Dr. A. Novelli), 691
- Affleck, H.: Appointed scientific officer, Federation of Malaya, 194
- Africa, a Study in Tropical Development (F. L. Dudley Stamp), review by R. W. Steel, 369
- Africa South of the Sahara, Scientific Council for: Publication No. 4, Maps of Africa South of the Sahara, 428
- Report for 1952-53, 1129
- Africa Surveyed, review by R. W. Steel, 369
- Africa (Central): University Education in, 1007
- Africa (East), 1947-1956: A Survey of Research and Scientific Services in (Dr. E. B. Worthington), 65
- Africa (East) High Commission: Paper No. 6, A Survey of Research and Scientific Services in East Africa, 1947-1956 (Dr. E. B. Worthington), 65
- Appointment of M. S. Brooks as statistician, 112
- Appointment of J. Roffey as scientific officer (entomologist), 112
- Appointment of P. S. Corbet as scientific officer, 194
- Appointment of C. C. Draper as medical research officer, grade 2, 194
- Appointment of J. Lucas as fisheries officer, 194
- Appointment of F. H. Talbot as scientific officer, 570
- Appointment of H. A. W. Southon as scientific officer (entomologist), East Africa Trade and Trypanosomiasis Research and Reclamation Organization, 570
- Appointment of J. L. Williams as statistician, 760
- Africa (East) Trade and Trypanosomiasis Research and Reclamation Organization: Appointment of H. A. W. Southon as scientific officer (entomologist), 570
- Africa (South): Flake-Tool Cultures in, 1214

- Africa (Union of South): Inhore Surface Currents on the West Coast of the (Dr. A. J. Clowes), 1003
- African Art: Webster Plate Collection of (William Fagg), 665
- African Lakes: Speciation of Fishes in (Dr. E. B. Worthington), 1064
- African (South) National Committee on Geochronology: First Meeting of the, 384
- African (West): 'Beef,' review by Dr. L. Harrison Matthews, 907
- African (West) Cacao Research Institute, Gold Coast: Appointment of W. T. Dale as senior plant pathologist, 112
- Report for 1952-53, 1129
- African (West) Institute for Oil Palm Research: Publication of a Journal, 19
- After-Effects of X-Irradiation of Deoxyribonucleic Acid (Dr. B. E. Conway), 597
- Age of Election to the Royal Society (Prof. A. V. Hill), 758
- Age-Limits and Working Life, 275
- Aghoramurthy, K.: Awarded an Overseas Scholarship for 1954 by the Royal Commission for the Exhibition of 1851, 1216
- Agrall, Iver: Estradiol and Testosterone Propionate as Mitotic Inhibitors during Embryogenesis, 172
- Agricultural Botany at Reading, 694
- Agricultural Botany, National Institute of: Conference on Varieties in relation to Crop Production, 198
- Agricultural Chemistry (Prof. Donald E. H. Frear), Vols. 1 and 2, review by Prof. H. D. Kay, 94
- Agricultural Colleges in Britain: Grant-aided (Ministry of Agriculture and Fisheries Committee to inspect), 1170
- Agricultural Contractors Association (British), and others: National Weed Control Conference, 147
- Agricultural Crops—Quality versus Quantity (Dr. G. D. H. Bell), 198
- Agricultural Department, Nigeria: Appointment of R. F. A. L. Reed as principal of schools, Western Region, 194
- Agricultural Department, Somaliland Protectorate: Appointment of N. R. Quill as development officer, 112
- Agricultural Education: Report of the Working Party on (Ministry of Agriculture and Fisheries), 705
- Agricultural Education in Great Britain (H. W. Gardner), 705
- Agricultural History Review, Vol. 1 (British Agricultural History Society), 895
- Agricultural Industries, International Commission of: Tenth International Congress of Agricultural and Food Industries, 339
- Agricultural Products and their By-products: New Developments in the Utilization as Food of Fish and (Aberdeen Section and the Food and Agriculture Groups of the Society of Chemical Industry and the Scottish Branch of the Institute of Biology Conference on), 339
- Agricultural Research: Careers in (Agricultural Research Council), 429
- Training Grants, Studentships and Fellowships in (Agricultural Research Council), 429
- Agricultural Research Council: Report Series No. 13, Antibiotics in Pig Food, 22
- Appointment of Dr. R. Braude as adviser on pig research, 385
- Careers in Agricultural Research—Training Grants, Studentships and Fellowships, 429
- Establishment of a Unit of Statistics within the University of Aberdeen, 569
- Appointment of David Lowe and J. N. Ritchie as members, 807
- Agricultural Research Council, and others: National Weed Control Conference, 147
- Australian and United Kingdom Postgraduate Research Studentships available in Australia, 429
- Agricultural Scholarships: Postgraduate (Ministry of Agriculture and Fisheries), 429
- Agricultural Soils: Nematode-destroying Fungi in (Dr. C. L. Duddington), 500
- Agricultural Subjects: Postgraduate Scholarships in (Ministry of Agriculture and Fisheries and the Department of Agriculture for Scotland), 385
- Agricultural and Food Industries: Tenth International Congress of (International Commission of Agricultural Industries), 339
- Agricultural and Medical Research: Statistical Tables for Biological, (Sir Ronald A. Fisher and Dr. Frank Yates), fourth edition, review by Prof. J. H. Gaddum, 183
- Agriculture: Chemistry and, review by Prof. H. D. Kay, 94
- The Early Days of, review by Sir John Russell, 916
- Legumes in (Report of the United Nations Food and Agriculture Organization), 243
- Lime in, review by W. N. Townsend, 6
- Toxic Chemicals in, and their Effect on Foodstuffs (Dr. Francis Aylward), 1063
- Use of Aircraft in (Organization for European Economic Co-operation, Technical Assistance Mission No. 107), 617
- Agriculture (British): The Use of Lime in (H. W. Gardner and H. V. Garner), review by W. N. Townsend, 6
- Agriculture (Scottish): Meteorology and (Royal Meteorological Society Symposium on), 1026
- Agriculture in Great Britain, 662
- Agriculture in Iraq: Census of (Dr. K. G. Fenehon), 1029
- Agriculture at Nottingham, 756
- Agriculture in the University of Aberdeen, 241
- Agriculture, Department of, Canada: Annual Report of the Director of Science Service for 1952-53, 758
- Agriculture, Department of, Jamaica: Appointment of D. Clay as veterinary officer, 760
- Agriculture, Department of, North Borneo: Appointment of A. W. Allen as soil scientist, 194
- Agriculture, Department of, Nyassaland: Appointment of R. A. Wood as chemist, 194
- Agriculture for Scotland, Department of (Ministry of Agriculture and Fisheries and the): Postgraduate Scholarships in agricultural subjects, 385
- Report of the Advisory Committee on Myxomatosis, 856
- Agriculture and Fisheries, Ministry of: Scholarships, 195
- Postgraduate Agricultural Scholarships, 429
- Recruitment of Sir James Scott Watson as chief scientific and agricultural adviser, 662
- Appointment of Prof. H. G. Sanders as chief agricultural and scientific adviser, 662
- Report of the Working Party on Agricultural Education, 705
- Committee to inspect Grant-aided Agricultural Colleges in Britain, 1170
- Agriculture and Fisheries, Ministry of, and the Department of Agriculture for Scotland: Postgraduate Scholarships in agricultural subjects, 385
- Report of the Advisory Committee on Myxomatosis, 856
- Agriculture and Fisheries, Ministry of, and others: National Weed Control Conference, 147
- Agr, Vaughn: Motion of the Storm-D Regions, 445
- Ahlers, N. H. E., and others: Spectroscopic Examination of Punic Acid, 1045
- Ahlfors, Prof. Lars V.: Complex Analysis, an Introduction to the Theory of Analytic Functions of One Complex Variable, review, 558
- Ahmad, Dr. Majeed, and Khan, Azeem: Polyametic Zygotas as a Source of Polyploidy and Irregular Repos in Yeast, 133
- Air: Detection of Free Hydroxyl Radicals during the Oxidation of Cellulose in (R. Holden), 559
- Geography from the (F. Walker), review by D. W. Bishopp, 231
- Air Ministry (Meteorological Office): Annual Report of the Director of the Meteorological Office for 1952-53, 200
- Averages of Temperature for Great Britain and Northern Ireland 1921-50, 813
- Averages of Bright Sunshine for Great Britain and Northern Ireland 1921-50, 813
- Air Transportation: Human Factors in (Prof. Ross A. McFarland), review by Alec Rodger, 654
- Air—Water Interface: Bursting of Bubbles at an (D. C. Blanchard), 1048; (Prof. D. M. Newitt), 1048
- Airborne Magnetic Surveys (Royal Astronomical Society Geophysical Discussion on), 281
- Aircraft in Agriculture: Use of (Organization for European Economic Co-operation, Technical Assistance Mission No. 107), 617
- Almy and Son (Leeds), Ltd., Wm.: Gift of £200 a year for seven years to the University of Leeds, for scholarships in concrete technology, 570
- 'Aka-Aka' of Silkworm: Abnormal Accumulation of 3-Hydroxykynurenine in the Mutant (Katsuhiko Makino, Hitoshi Takahashi, Kiyoo Setoh and Kaoru Inagumi), 586
- Alkamas, Hideo, and others: Electrical Conductivity of the Perylene-Bromine Complex, 168
- Alshurst, B. C.: Appointed agricultural officer, Tanganyika, 896
- Alkars, Sir Wallace: Elected president of the International Institute for the Conservation of Museum Objects, 20
- Beta-Alanine Peptides, and Nucleosides: Zone Electrophoresis of, Muscle Extracts—Separation of Phosphocreatine, Creatine, (Dr. Albert Wolleberg), 205
- Albert, Prof. Adrien: The Monosubstituted Pteridines, 1046
- Recent Advances in the Chemistry and Biology of the Pteridines, 1176
- Albert I. of Monaco: Commemorative Medal of Prince (Prox Manley-Bendall), awarded for 1954 to Captain de Corvaise G. Houot and Engineer Officer P. Wilim, 1217
- Alchemy: Astrology and (Mark Graubard), review, 701
- Alchemy and Early Chemistry, Society for the Study of: Ambix, Vol. 5, Parts 1 and 2, 112
- Alcock, J. F.: Gas Absorption, 1029
- Alcohol Determination and its Medico-legal Aspects (Dr. D. W. Kent-Jones), 760
- Alcoholic Fermentations: Yeasts and (Society for Applied Bacteriology Symposium on), 1026
- Alcoholic Intoxication: Chemical Diagnosis of (J. J. Prag), 1213
- Aldehydes as Specific Chromatographic Colour Reagents for Amino Acids: Aromatic (G. Cifroni and J. Giltrow), 314
- Alder, F. E.: Weed Control, 148
- Aleucones Layer in Barley (J. S. Seward), 344
- Alexander, Dr. P., and Charlesby, Dr. A.: Energy Transfer in Macromolecules Exposed to Ionizing Radiations, 578
- Alfrey, Dr. G. F.: Luminescence of Inorganic Phosphors, 1077
- Alga Chlamydomonas eugametos: An Antagonist of the Steroid Hormone Rytin in the Green—Ombuicide—7-4-Dimethyl-rytin (Dr. Franz Moewas and Dr. Venancio Deulofeu), 218
- Algae: Culture of, review by Dr. E. G. Pringsheim, 907
- The Metabolism of (Dr. G. E. Fogg), review by Prof. J. Myers, 280
- Physiology of the, review by Prof. J. Myers, 280
- Algae (Marine): Observations on the Iodo-Amino-Acids of, using Iodine-131 (Richard Scott), 1098
- Algal Culture, from Laboratory to Pilot Plant (edited by John S. Burlew), review by Dr. E. G. Pringsheim, 907
- Algal Cytology: Leucocytin in (Prof. E. G. Pringsheim), 775
- Algal Physiology and Biochemistry (British Physiological Society Symposium on), 434
- Algeri, M. O.: Gas Absorption, 1028
- Algebra: Linear, and Matrix Theory (Prof. Robert R. Stoll), review by L.S.G., 142
- Linear, and Projective Geometry (Reinhold Bear), review by Prof. H. T. H. Paggio, 934
- Algebraic Topology: Foundations of (Samuel Eilenberg and Norman Steenrod), review by Dr. R. G. Cooke, 934
- Alladi Meahs: Separation and Identification of, on Paper Chromatograms (Alan E. Steel), 315
- Alkaline Phosphatase: Diffusion of, to Characteristic Intracytoplasmic Sites of Activity (R. Barter), 1233
- Phase-Contrast Microscopy of the Gonorrhea Reaction for (Dr. N. M. Hancock and Evelyn Nicholas), 951
- A Quantitative Method for Enzyme Cytochemistry applied to (H. G. Davies, R. Barter and Prof. J. F. Danielli), 1234
- Alkaline Phosphatase in the Adrenal Cortex of the Guinea Pig: Effect of Experimental Tuberculosis on the Distribution of (Dr. Amyr B. Kur), 210
- Alkaline Phosphatase and Non-specific Esterase: Histological Demonstration of, by Azo-dye Methods (Dr. J. F. Burton), 642
- Alkaloid Extract in Toxicology: Paper Chromatographic Examination of the (Dr. A. S. Curry and H. Powell), 1143

- Alkaloids: The (edited by R. H. F. Manske and H. L. Holmes), Vol. 2, review by Dr. Harold King, 93
- Alkaloids (Plant): Handbook of the, review by Dr. Harold King, 93
- Alkaloids in Germinating Seeds of *Atropa belladonna* (Dr. P. Reinouts van Hage), 692
- Allen, M. E. (Ashour, Dr. W. E., and): Shot-hole Disease of Stone Fruits caused by *Clorostromum carpophilum*, 456
- Allen, J. K.: Elected a Fellow of the Royal Society of Edinburgh, 474
- Allen, A. W.: Appointed soil scientist, Department of Agriculture, North Borneo, 194
- Allen, Sir George: Appointed secretary to the British Association for the Advancement of Science, 290; work of, 290
- Allen, Dr. L. A.: Dextran and its Applications, 235
- Allibone, Dr. T. E.: Obituary of Dr. Karl B. McEachron, 381
- Allis, Prof. William P.; and Herlin, Prof. Melvin A.: Thermodynamics and Statistical Mechanics, review, 702
- Alum paradoxum in Gloucestershire: Distribution and Chromosome Number of (D. M. Barling), 877
- Allometric Growth in the Nematode (William G. Inglis), 957
- Alloys: Oxidation of Metals and (Dr. O. Kubaschewski and B. E. Hopkins), review by Prof. A. G. Quinlan, 922
- Alsopp, A.: Juvenile Stages of Plants and the Nutritional Status of the Shoot Apex, 1032
- Almond, Mary, and others: The Velocity Distribution of Sporadic Meteors, 4, Extinction to Magnitude +8 and Final Conclusions, 861
- Alper, Tikvah (Ebert, Michael, and): Influence of Dissolved Gases on Hydrogen Peroxide Formation and Bacteriophage Inactivation by Radiation, 987
- Alpha-Particle Counting: Precision (Mrs. K. M. Glover and G. R. Hall), 991
- Alpha- and Beta-Forms of Poly-L-Alanine (Dr. C. H. Bamford, L. Brown, Dr. A. Elliott, W. E. Hanby and I. F. Trotter), 27
- Alternating Current Wave Forms (Philip Kemp), second edition, review, 515
- Altman, Dr. K. I. (Frankland, Dr. T. A. J., and): Phospholipid Partition and Turnover in Human Red Cells, 870
- Altman, Dr. R. F. A.: Steroidal Saponins in Amazonian Plants, 1098
- Aluminium Development Association: Research Scholarship, 896
- Offer of a Research Scholarship to the Institution of Structural Engineers, 1125
- Alvarez, Ediberto F. (Lora-Tumayo, Prof. M., and): Coenzyme of Kidney Phosphatase, 548
- Amaldi, Prof. E., and others: Symbols for Fundamental Particles, 123
- Amateur Scientist in Britain (R. Brightman), (1), 560; (2), 609
- Amazonian Plants: Steroidal Saponins In (Dr. R. F. A. Altman), 1098
- Ambur, Vol. 5, Parts 1 and 2 (Society for the Study of Alchemy and Early Chemistry), 112
- Amelindor, S.: Direct Observation of Polygonization in Rocksalt, 993
- American Academy of Arts and Sciences: Election of Prof. J. E. Burchard as president, 978
- Election of Foreign Honorary Members, 978
- American Association for the Advancement of Science: Newcomb Cleveland Prize awarded to Prof. Barry Commoner, 336
- Theobald Smith Award in Medical Sciences for 1953 awarded to Dr. Irving M. London, 336
- American Association of Scientific Workers: Celebration of Prof. Albert Einstein's seventy-fifth birthday, 430
- American Institute of Electrical Engineers, and others: Proceedings of the Western Computer Conference held by the Joint IRE-AIEE-ACM Computer Conference Committee, Los Angeles, 200
- American Meteorological Society, and others: Symposium on Radio-Meteorology, 761
- American Physical Society: Cumulative Index for 1921-50 of the *Physical Review* (compiled by Prof. J. W. Bochte), 618
- American Scientists, Federation of: Survey on Visas to the United States for Scientific Workers, 427
- American Society of Agronomy, and others: Conference on Soil Microbiology, 896
- American Society of Mechanical Engineers, and others: Celebration of the contribution by engineers to the development of powered flight, 150
- Citation awarded to Dr. W. F. Durand for his services to engineering and aviation, 150
- American Society for Testing Materials: Second Annual Meeting of Committee E-14 on Mass Spectrometry, 667
- American Society for Testing Materials and the Institute of Petroleum: ASTM-IP Petroleum Measurement Tables, British edition, British (Imperial) Units of Measurement, review by H. B. Milner, 515
- American Telephone and Telegraph Co.: Frank B. Jewett Fellowship Awards, 1075
- American (Central) Orchids, review by V. S. Summerhayes, 181

 Australian Scientific Liaison Office, London: Return of J. E. Cummins to Australia after six years as chief scientific liaison officer, 855
 Appointment of Walter Ives as chief scientific liaison officer, 855
 Australian and New Zealand Association for the Advancement of Science: Report of the Twenty-ninth Meeting, 242
 Australian and United Kingdom Postgraduate Research Studentships tenable in Australia (Commonwealth Scientific and Industrial Research Organization, the Department of Scientific and Industrial Research and the Agricultural Research Council), 429
 Australopithecines: *Prithacanthropus*, *Megacanthropus* and the (Prof. G. H. R. von Koenigswald), 795
 Austrian Chemical Association (Spectrochemistry and Colorimetry Group): International Colloquium on Spectroscopy, 245
 Autodigestion of Papain: Formation of Enzymatically Active, Dialysable Fragments during (Dr. Gertrude E. Perlmann), 406
 Automatic Digital Computing Machines: Summer School in Programme Design for (University Mathematical Laboratory, Cambridge), 981
 Automotive Engineers, Society of, and others: Celebration of the contribution by engineers to the development of powered flight, 150
 Citation awarded to Dr. W. F. Durand for his services to engineering and aviation, 150
 Autoradiography: Carbon-14 β -Track, of High Resolution (Dr. M. C. Walters and R. Thame), 1146
 Detection of Adenine Carbon-14 in Deoxyribonucleic Acid by (Dr. L. G. Laytha), 587
 Microradiography and (Scientific and Technical Group of the Royal Photographic Society Symposium on), 387
 Autrum, H.: Acoustics of Orthoptera, 1219
 Awdin in Normal Urine: Identity of (O. P. Wieland, R. S. de Ropp and Mrs. J. Avenar), 776
 Auzan and Mushroom Growth (I. M. Fraser), 664
 Auxotrophic Mutants of *Erwinia aversae*: Virulence of (Dr. E. D. Garber and Adeline J. Hackett), 88
 Avenar, Mrs. J., and others: Identity of Auzan in Normal Urine, 776
 Averages of Bright Sunshine and Temperature for Great Britain and Northern Ireland, 813
 Aviation: Health and Safety in, *review* by Alec Rodger, 654
 Aysc, P. G., and others: A Crystalline Material with Xanthine Oxidase Activity, 1230
 Axon, Dr. H. J. (Wright, J. K., and) Clinical and Metallurgical Observations on the Corrosion of Stainless Steel Screws used in Orthopaedic Surgery, 1186
 Ayres, R. P.: Gas Absorption, 1029
 Aylward, Dr. Francis: Toxic Chemicals in Agriculture and their Effect on Foodstuffs, 1063
 The Borough Polytechnic, London—New Extension Building, 1076
 8-Azaguanine: Incorporation of, into Nucleic Acids (Dr. Ilse Larnicku, Dr. R. E. F. Matthews and Dr. J. D. Smith), 346
 Azaserine, a New Tumour-Inhibitory Substance—Studies with Crocker Mouse Sarcoma 180 (Dr. C. Chester Stock, H. Christine Reilly, Sonja M. Buckley, Donald A. Clarke and C. P. Rhoads), 71
 Antibiotic Studies of Azaserine (John Ehrlich, Luca E. Anderson, George L. Coffey, Arthur B. Hillegas, Mildred P. Knudsen, Harold J. Koepsell, Dorothy L. Kohberger and Julian E. Oyler), 72
 Isolation and Characterization of Azaserine (Quentin R. Bartz, Carole C. Elder, Roger P. Frohardt, Salvatore A. Fusari, Theodore H. Huskell, Doris W. Johansen and Albert Ryder), 72
 Azo-compounds: Carcinogenic (Dr. G. M. Badger, G. E. Lewis and R. T. W. Reid), 313
 Azo-dye Methods: Histological Demonstration of Alkaline Phosphatase and Non-Specific Esterase by (Dr. J. F. Burton), 642
 Azotobacter: Effect of Oxygen on the Fixation of Nitrogen by (C. A. Parker), 780
 BAADE, Dr. Walter W.: Awarded the Gold Medal of the Royal Astronomical Society, 112
 Babcock, H.W.: Elected a member of the National Academy of Sciences, Washington, 1173
 Bacharach, A. L.: Dextran and its Applications, 237

- Bacilli (Non-pathogenic Asporogenous): A Method for the Rapid Differentiation of certain (Dr. J. M. Sheehan and W. Hodgkiss), 208
- Bacillus anthracis*: Observations on Experimental Anthrax—Demonstration of a Specific Lethal Factor produced *in vivo* by (H. Smith and J. Kappes), 869
- Bacterioid: Structure of (I. M. Lockhart, Dr. G. G. P. Newton and Dr. E. P. Abraham), 536
- Beck Grant of the Royal Geographical Society awarded to Comdr. G. S. Ritchie, 569
- Becker, Prof. H. J.: Elected a correspondent in the Chemistry Section of the Paris Académie des Sciences, 17
- Becon, Dr. G. E.: Newton Diffraction Work, 21
- Becon, Dr. G. E. (Passe, R. S., and): Ferroelectric Structure of Potassium Dihydrogen Phosphate, 443
- Becon (Roger) in Life and Legend (E. Westacott), review by Dr. F. Sherwood Taylor, 747
- Bacteria: Stimulation of certain, by Raw Milk (J. E. Auchter), 491
- Bacterial Generic Names: Abbreviation of, 663
- Bacterial Nuclei: Electron Microscopic Observations on (Dr. J. R. G. Bradford), 184
- Bacterial Toxin paralyzing Silk-worm Larvae (T. A. Angus), 545
- Bacteriology at Aberdeen, 710
- Bacteriology (Applied), Society for: Symposium on Microbial Spoilage in Industrial Materials, 102
- Annual Meeting and Summer Conference, 1026
- Symposium on Yeasts and Alcoholic Fermentations, 1026
- Bacteriology (Applied), Society for, and the Microbiology Group of the Society of Chemical Industry: Symposium on Industrial Methods of Sterilization, 333
- Bacteriophage: Dependence of X-Ray Sensitivity of, on Phase State and Temperature (Prof. Thomas H. Wood), 641
- An Inhibitor of the Lyso of *Staphylococcus aureus* by (A. M. Hood and E. J. L. Lowbury), 433
- Bacteriophage Inactivation by Radiation: Influence of Dissolved Gases on Hydrogen Peroxide Formation and (Michael Ebert and Tikvah Alper), 987
- Bacteriophage and Heredity (Dr. J. S. K. Boyd), 1050
- Badger, Dr. G. M., and others: Carcinogenic Azo-compounds, 313
- Badhwar, Rattan Lal, and others: Poisonous Plants of India, Vol. I, review by Dr. N. L. Bor, 745
- Beer, Reinhold: Linear Algebra and Projective Geometry, review by Prof. H. T. H. Pangro, 934
- Babadur, Dr. Krishna: Photomynthesis of Amino-Acids from Paraformaldehyde and Potassium Nitrate, 1141
- Bailey, Miss A. I.: Awarded a Senior Studentship for 1954 by the Royal Commission for the Exhibition of 1851, 1216
- Bailey, C. E. G.: Poetry and Science, 113
- Bailey, G. L., and others: Rate of Milk Secretion in Dairy Cattle in the intervals between Consecutive Milkings, 404
- Bailey, I. W., and others: Plant Genera, their Nature and Definition, review by Dr. W. B. Turill, 908
- Bailey, Dr. Kenneth: Proteins and Enzymes, review, 607
- Bailey, Dr. Kenneth (edited by Neurath, Hans, and): The Proteins: Chemistry, Biological Activity and Methods, Vol. I, Part A, and Vol. I, Part B, review by Dr. D. P. Riley, 1059
- Bailey, S. W.: Hardness of Arthropod Mouthparts, 503
- Bain, E. C.: Elected a member of the National Academy of Sciences, Washington, 1173
- Bain, K. H.: Appointed fisheries officer, Federation of Malaya, 760
- Bain, Dr. R. V. S.: Vaccination against Haemorrhagic Septicæmia of Bovines, 584
- Bainbridge, Richard: Plankton Studies, 337
- Baker (George Fisher) Non-resident Lectureship in Chemistry at Cornell University (Prof. J. Monteth Robertson), review by Prof. K. Lonsdale, 964
- Baker, Dr. John R.: Abraham Tremblay of Geneva, Scientist and Philosopher, 1710-1784, review by Prof. Charles Singer, 557
- Baker, R. E. D., and Simmonds, Dr. N. W.: Bananas, 980
- Baker, Prof. W.: Obituary of Lady Robinson, 566
- Bakerian Lecture of the Royal Society (Prof. A. R. Todd), 385
- Bakowski, S.: Gas Absorption, 1028
- Balane in Populations: Experimental Demonstrations of (Dr. A. J. Nicholson), 862
- Balchun, Dr. W. G. V.: The Geographical Association, 99
- Awarded the Gill Memorial of the Royal Geographical Society, 569
- Appointed to the newly established chair of geography at University College, Swansea, 756; work of, 756
- Baldwin, J. E., and Dewhirst, D. W.: Position and Identification of a Bright Extended Radio Source in Gemma, 164
- Baldwin, J. E., and Elmore, B.: Radio Emission from the Perseus Cluster, 818
- Baldwin, T. H.: Education in the African Colonies, 198
- Balfour-Browne, Mrs. F. L.: A New Fungus Flora, review, 52
- Bali, J. G., and others: Some Physical Properties of Metallic Plutonium, 535
- Bell, N. G.: Horizontal Disposition of Rhizomes, 298
- Bellard, B. G.: Appointed to the additional post of vice-president (scientific), of the National Research Council of Canada, 894; work of, 894
- Bells, Prof. A. K.: Elected a member of the National Academy of Sciences, Washington, 1173
- Bells, Dr. W. Lawrence: The Yields of a Crop, review by Prof. S. C. Harland, 6
- Bembes, L. L.: Five-Membered Heterocyclic Compounds with Nitrogen and Sulfur or Nitrogen, Sulfur and Oxygen (except Thiazole), review by Dr. L. D. Loudon, 930
- Barnford, Dr. C. H., and others: Alpha- and Beta-Forms of Poly-L-Alanine, 27
- Banana: Growth-promoting Substances in the Ovary and Immature Fruit of the (Prof. F. C. Steward and Dr. N. W. Simmonds), 1083
- Bananas (R. E. D. Baker and Dr. N. W. Simmonds), 980; (A. Fahn), 981
- Anthracene in (Dr. N. W. Simmonds), 402
- Banbury, G. H.: Processes controlling Zygospore Formation and Zygocarpium in *Mucor mucido* Briffeld, 499
- Band Spectra of Diatomic Molecules, review by Dr. A. G. Geydon, 417
- Banks, T. E., and others: Estimation of Zinc in Biological Specimens—Determination of Zinc-65, 348
- Banta Mothers on a High-Maze Diet: Low Nicotin Concentration in the Breast Milk of (Dr. A. R. P. Walker), 405
- Baranov, V., and Tassenov, J.: Gravity Problems in Exploration Geophysics, 246
- Barbados, West Indies: Submarine Landslips off the Coast of Puerto Rico and (Raoul C. Mitchell), 119
- Trans-Atlantic Profile of Total Magnetic Intensity and Topography, from Dakar to (B. C. Heezen, M. Ewing and E. T. Miller), 528
- Barber, Bernard: Science and the Social Order, review by R. Brighman, 5
- Barber, Prof. H. N.: Genetic Polymorphism in the Rabbit in Tasmania, 1222
- Barclay-Smith, Miss Phyllis: Awarded the Gold Medal of the Swedish Dynastidaforsamlingen Riksförbundet, 339
- Bardeen, Prof. J.: Elected a member of the National Academy of Sciences, Washington, 1173
- Bardeen, Dr. S. E.: High-Energy Accelerators, 1127
- Barer, Dr. R.: Modern Developments in Microscopy, 158
- Lecture Notes on the Use of the Microscope, review by Prof. L. C. Martin, 1158
- Barer, Dr. R., and Tlaczky, S.: Refractive Index of Concentrated Protein Solutions, 821
- Barnum Triamite: Anomalous Temperature Coefficient of Permittivity in (K. W. Plesner and K. A. Cook), 692
- Barker, K. H.: Cosmic Radiation, 1128
- Barley: Aleurone Layer in (J. Sawicki), 344
- Barley Roots: Fixation of Carbon Dioxide by Excised (L. W. Poel), 63
- Barling, D. M.: Distribution and Chromosome Number of *Allium paradoxum* in Gloucestershire, 877
- Barlow, Prof. H. M.: Application of the Hall Effect in a Semi-conductor to the Measurement of Power in an Electromagnetic Field, 41
- Barnard, Dr. G. P.: Modern Mass Spectrometry, review by Dr. D. F. Bracher, 605
- Barnard, Dr. Tom: Title of reader in micropaleontology in the University of London conferred on, 64
- Barnes, Right Rev. E. W.: Obituary by Prof. F. J. M. Stratton, 15
- Barnes, H. (Rothschild, Lord, and): Osmotic Pressure of Bull Semen Diluents, 636
- Barnes, Dr. J. A.: Title of reader in anthropology in the University of London conferred on, 64
- Barnes, R. F.: Appointed scientific officer (plant pathologist), Jamaica, 194
- Barnett, Sir George: The Scientific Study of Human Work in Industry, 983
- Barnett, S. A., and Manly, Brenda M.: Breeding of Mice at -3° C., 353
- Barnley, G. F.: Weed Control, 149
- Baron, Dr. D. N.: Appointed to the University of London readership in chemical pathology at the Royal Free Hospital School of Medicine, 619
- Baron, Dr. D. N., and Abelson, Dr. Denis: Cortisone and Hydrocortisone in Cerebrospinal Fluid, 174
- Barnall, Dr. H.: Engineering Dimensional Metrology, 294
- Barnett, F. C. (Brimley, R. C., and): Practical Chromatography, review by A. T. James, 1159
- Barnett, J., and Lemberg, Dr. R.: Prosthetic Group of Cytochrome a_1 , 213
- Barrow, R. F., et autres (établi par): Tables de constantes et données numériques, Vol. 5, Constantes sélectionnées, Atlas des longueurs d'onde caractéristiques des bandes d'émission et d'absorption des molécules diatomiques, review by Dr. A. G. Geydon, 417
- Barter, R.: Diffusion of Alkaline Phosphates to Characteristic Intracellular Sites of Activity, 1233
- Barter, R., and others: A Quantitative Method for Enzyme Cytochemistry applied to Alkaline Phosphatase, 1234
- Bartlett, Sir Frederic: The Scientific Study of Human Work in Industry, 984
- Barton, Dr. A. W.: Shortage of Science Teachers in Schools, 196
- Barton, Prof. D. H. R.: Elected a Fellow of the Royal Society, 567
- Bartz, Quantin R., and others: Azaserine, a New Tumour-Inhibitory Substance—Isolation and Characterization of Azaserine, 72
- Barus, P. K. (Wight, W., and): Morphological Basis of Quality in Tea, 630
- Bashford—Adams Method for the Numerical Solution of Differential Equations (Dr. Andrew D. Booth), 635
- Basophil Components of Cytoplasm (Histochemical Society Symposium on), 245
- Basu, Dr. B. C.: Elected a Fellow of the National Institute of Sciences of India, 474
- Batchelor, Dr. G. K.: The Theory of Homogeneous Turbulence, review by Prof. M. J. Lighthill, 746
- Bates, Prof. D. R.: The Rocket as a Research Tool, review, 697
- Excitation and Collision Phenomena, 1128
- Bath Technical College: Resignation of H. B. Toft as principal, 714
- Bathypelagic Nemertean Worm: An Acidogenic Carotenoid in a (Prof. Denis L. Fox), 583
- Beccace, Prof. T.: Determination of Atomic Masses by the Pykno-X-Ray Method, 345
- Baty, J. E.: Engineering Dimensional Metrology, 294
- Bauer, S. H.: Fast Chemical Reactions, 1163
- Beudantic: Composition and Origin of the Antrim Limestones and (V. A. Eyles), 812
- Bawa, Sukh Dev Ray, and others: Are Spindle Fibres and Mid-body Granules Artefacts?, 312
- Bawden, F. C.: The Study of Viruses, review, 324
- Baxendale, Dr. J. H.: Inorganic Kinetics and Reactions, 672
- B.B.C. from Writun (Lord Simoa), 509
- B.B.C. Science Survey: Work of Dr. Archie Clow, 191
- Beagle, H.M.S.: Journal of Researches into the Geology and Natural History of the various Countries visited by (Charles Darwin), facsimile reprint of the first edition, review by Dr. W. E. Swinton, 927
- Beales, A. C. F.: Title of reader in education in the University of London conferred on, 667
- Bean, B. R.: Radio-Meteorology, 762
- Bean Shoot: Symmetry of the (K. J. Dormer), 714
- Beer, R. S.: Structure of Proteins, 57

- Beatty, Dr. R. A.: Recent Advances In Animal Morphogenesis, 520
- Beaven, Dr. G. H., and White, Dr. J. C.: Oxidation of Phenylhydrazines in the Presence of Oxyhaemoglobin and the Origin of Hæm Bodies in Erythrocytes, 389
- Beaver, Sir Hugh: Appointed chairman of the Advisory Council for Scientific and Industrial Research, 1171
- Beazley, Sir John Davidson: Elected a Foreign Honorary Member of the American Academy of Arts and Sciences, 978
- Beck, A. H., and Brisbane, A. D.: Awarded a Radio Industry Council Premium for Technical Writing, 384
- Bediect, A. H., and Cary, A. F.: Stereochemistry of certain Analgesics, 1231
- Bee Behaviour, review by Dr. H. Kalmus, 96
- 'Beef': West African, review by Dr. L. Harrison Matthews, 907
- Bees (Honey-): The Behaviour and Social Life of (C. R. Ribbands), review by Dr. H. Kalmus, 96
- Beet Eelworm: Hydrostatic Pressure-Deficiency and the Emergence of Larvae from Cysts of the (H. R. Wallace), 502
- Beede (Confused Floor): Carnitine (Vitamin B₇) as a Nutritional Requirement for the (Elery W. French and Prof. G. Fraenkel), 173
- Bevers, Dr. C. A., and Rastick, B.: Properties of the Calcium Phosphates, 542
- Bevers, Harry, and Gibbs, Martin: Participation of the Oxidative Pathway in Yeast Respiration, 640
- Behaviour: Bee, review by Dr. H. Kalmus, 96
- Behaviour of *Aphis fabae* Scop.: Effect of Flight on (Bruce Johnson), 831
- Behaviour of Birds: Social, review by Sir Landsborough Thomson, 905
- Behaviour and Social Life of Honeybees (C. R. Ribbands), review by Dr. H. Kalmus, 96
- Behaviour Patterns: Adult Anopheles—a Suggested Classification (R. Seckler-White), 730
- Behrend, Dr. Hilde: Limits to a Firm's Control of Labour Turnover, 379, 1150
- Bert Memorial Fellowships for Medical Research: Awards, 981
- Bert Memorial Trust: Resignation of Prof. T. R. Elliott from the Board, 981
- * Appointment of Sir Alan Drury to the Board, 981
- Belcher, Dr. R.: Title of reader in analytical chemistry in the University of Birmingham conferred on, 1217
- Belding, H. S., and Hatch, T. F.: The Scientific Study of Human Work in Industry, 983
- Behradske, Dr. Jan: Temperature and Rate of Enzyme Action, 70
- Belfast Medical School: Institute of Clinical Science opened by Lord Wakehurst, 1208
- Belgian Congo: Boron Deficiency in Oil Palms in the Kasai Region of the (J. D. Fenwicks), 1097
- Flora of the, 854
- Bell, C. J. (O'Brien, P. A., and): Distribution of Radio-Frequency Brightness across the Solar Disk and the Derivation of a Model Corona, 219, erratum, 245
- Bell, Dr. G. D. H.: Agricultural Crops—Quality versus Quantity, 198
- Bell, R. P.: Five Chemical Reactions, 1162
- Bell Telephone Laboratories: Transformers Wound without Wire, 152
- Bellairs, F. R., and Arnova, W. A.: Radio-Meteorology, 762
- Bellairs, Dr. R.: Recent Advances in the Chemistry and Biology of the Psittacines, 1177
- Bellamy, Dr. L. J., and Brunch, R. F.: Infra-red Spectra of Fluorinated Hydrocarbons, 633
- Belyankin, Prof. D. S.: Obituary by Dr. S. I. Tomkasev, 472
- Bendall, J. R.: Myokinesis as a Relaxing Factor in Muscle, 548
- Bengtsson, Dr. Lars Ph.: Absorption of Phosphorus-32 from the Rabbit Vagina under various Hormonal Conditions, 954
- Benndorf, Prof. H.: Obituary by Prof. A. Székely, 335
- Bennet-Clark, Prof. T. A.: Obituary of Prof. H. H. Dixon, 239
- Bennett, E. W.: Appointed lecturer in the Department of Civil Engineering, University of Leeds, 1217
- Beatty, A. H., and Champion, Dr. F. C.: Some Effects of Neutron Irradiation of Diamond, 1087
- Penzon, J. E.: Awarded a Mond Nickel Fellowship for 1953, 64
- Bentonite Beds at Linnaskille, Sweden: 'Mixed Layer' Minerals from the Ordovician (Dr. Ann Marie Bystrom), 783
- Bentwich, Norman: The Rescue and Achievement of Refugee Scholars, review by Dr. H. E. Wimperley, 1201
- Benzene at -3° C.: Crystal Structure of (Prof. E. G. Cox and J. A. S. Smith), 73
- γ -Benzene Hexachloride in the Animal Body: Metabolism of (K. van Asperen and F. J. Oppenorth), 1000
- γ -Benzene Hexachloride In Susceptible and Resistant Houseflies: Metabolism of (F. J. Oppenorth), 1000
- Bernaldo, W. T., and others: Action of Peptone on Mast Cells of the Dog, 547
- Bergal, Prof. F., and others: A Crystalline Material with Xanthine Oxidase Activity, 1230
- Berger, Arne, and others: Reversible Inhibition of Pepsin by Polylysine, 998
- Bergmann, Dr. Ernst G., and Levinson, Zvi H.: Steroid Requirements of Housefly Larvae, 211
- Bergsagel, Dr. D. E.: Awarded a National Research Council of Canada Fellowship for Medical Research, 1216
- Berninger, Carl Chr.: Vulkanismus und andere Tiefenkräfte der Erde, review by D. W. Bishop, 1205
- Berkley, George, Bishop of Cloyne: The Works of, Vol. 5, Sirs, Three Letters to Thomas Prior, A Letter to the Rev. D. Hales, Further Thoughts on Tar-water, Varra (edited by Prof. T. E. Jessop), review by Prof. A. D. Ritchie, 416
- Bermuda Biological Station: Retirement of Dr. L. W. Hutchins from the directorship, 426
- Appointment of Dr. W. H. Sutcliffe, jun., as director, 426
- Grant from the U.S. National Science Foundation, mainly for Fellowships, 896
- Bernal, Prof. J. D.: Identification by X-Ray Crystallographic Techniques, 22
- Science and Industry in the Nineteenth Century, review by R. Brighman, 139
- Bernow, Prof. A.: Luminescence of Inorganic Phosphors, 1077
- Bernard, P.: Calcareous Flagellates In Deep-Sea Fertility and Sedimentation, 528
- Berndt, Prof. G.: Engineering Dimensional Metrology, 293
- Bernstein, L., and others: The Caval Sphincter in *Phoca vitulina* L., 86
- Berridge, Dr. N. J., and Briggs, C. A. E.: Electrophoresis of Group-Specific Extracts of Streptococci, 486
- Bertill, Prof. N. J.: Journey into Wonder, review by Dr. Alan J. Brook, 747
- Bershadsky, Z.: Gas Absorption, 1029
- Bessel Functions, Part 2, Functions of Positive Integer Order (British Association for the Advancement of Science Mathematical Tables, Vol. 10) (prepared by W. G. Biddle, L. J. Comrie, D. H. Sadler, J. C. P. Miller and A. J. Thompson), review by J. H. Pearce, 607
- Bessemer Gold Medal for 1954 of the Iron and Steel Institute awarded to Dr. T. P. Coldough, 862
- Beta-Forms of Poly-L-Alanine: Alpha- and (Dr. C. H. Bamford, L. Brown, Dr. A. Elliott, W. E. Hanby and I. F. Trotter), 27
- β -Track Autoradiography: Carbon-14, of High Resolution (Dr. M. C. Walters and R. Thoma), 1146
- Beveridge, Prof. W. I. B.: The Art of Scientific Investigation, second edition, review by Dr. A. S. Purves, 936
- Bhargava, B. N., and Naqvi, Ali M.: Very Long Sequences of Geomagnetic Activity and its Annual Variation, 498
- Bhattacharya, Dr. S. K.: Elected a Fellow of the National Institute of Sciences of India, 474
- Bhimber, Bhatnagar Singh, and others: Are Spindle Fibres and Mid-body Granules Artefacts?, 312
- Balobrzanski, Prof. C.: Obituary by Prof. Z. Klemensiewicz, 16
- Banco, I., and others: Genic Equilibrium of Microcythemia in some Italian Districts, 357
- Bibby, C.: The Training of Biologists, 897
- Bibliographical Centre, National, at Ankara, 811
- Bibliography, Turkish National Institute of: Bibliography of Articles appearing in Turkish Periodicals, 195
- Bibliography of Articles appearing in Turkish Periodicals (Turkish National Institute of Bibliography), 195
- Bibliography of Key Works for the Identification of the British Fauna and Flora (edited by Dr. John Smart and Dr. George Taylor), review by Prof. H. P. Moon and Prof. T. G. Tutin, 965
- Bibliography of Natural History, Society for the: Annual General Meeting, 525
- Election of Officers, 525
- Journal of the, 617
- Bibliography of Setonology (W. G. Milne), Vol. 14, Nos. 9-12, 713
- Bibliography and the History of Science (V. A. Eyles), 525
- Biblioteca Chemico-Mathematica: Socheran's, Third Supplement, review, 98
- Bicarbonate Content of the Blastocyst Fluid and Carbonic Anhydrase in the Pregnant Rabbit Uterus (Dr. C. Lutwak-Mann and Dr. H. Lasser), 268
- Bicentenary of Columbia University (Prof. L. C. Dunn), 703
- Bidder, Dr. G. P.: Obituary by Dr. C. F. A. Pantin, 802
- Bijl, W. van der, and Harrison, J. L.: Moonlight and the Pregnancy of Malaysian Forest Rats, 1002
- Bjvoet, Prof. J. M.: Structure of Optically Active Compounds in the Solid State, 898
- Bile (Ox): A Bile-soluble Metal Complex in (R. J. Garner), 451
- Bile-soluble Metal Complex in Ox Bile (R. J. Garner), 451
- Bilgic, Dr. E., and Ridout, M. S.: Transmission of Electrons and Holes across a Twin Boundary in Germanium, 496
- Briffingham, Dr. R. E.: Recent Advances in Animal Morphogenesis, 519
- Buland, Lord: Elected president of the Scottish Economic Society, 616
- Burns, A. L.: Education in the African Colonies, 198
- Bio-assay: Are Inbred Strains suitable for (Anne McLaren and Donald Michie), 686
- Biossary of Acetylcholine and 5-Hydroxytryptamine: Marine Invertebrate Preparations useful to the (Dr. John H. Walsh), 955
- Biochemical and Osmotic Properties of Skeletal Muscle Mitochondria (J. B. Chappell and Dr. S. V. Perry), 1094
- Biochemistry: Algal Physiology and (British Phycollogical Society Symposium on), 434
- Radiocarbon and some Applications in (Dr. E. Broda and Dr. L. Sverak), 676
- Biochemistry and Physiology: Isotopic Tracers in (Prof. Jacob Seck), review by Dr. William C. Hutchison, 910
- Biochemistry and Physiology of Nutrition (edited by Geoffrey H. Bourne and George W. Kidder), Vol. 1, review by Dr. D. P. Cuthbertson, 139
- Biodiames and Structural Colours: Animal (Dr. Denis L. Fox), review by Dr. E. F. Hartree, 909
- Biological Acetylation of α -Nicotinyl Hydrazide (Dr. Kazuaki Makino, Takeo Kinoshita and Tsuyoshi Itoh), 36
- Biological Action of Fast Protons: Probable Side-effect of Nuclear Reactions in the (Dr. Lars Ehrenberg and Dr. Göran Andersson), 1086
- Biological Council, 714
- Biological Interest: Reduction by X- and γ -Rays of some Substances of (Dr. Gabriel Stern and Dr. A. J. Swallow), 937
- Biological Properties: Synthesis of Fluoropyruvic Acid and some of its (J. Mayer and I. Blank), 126
- Biological Sciences, International Union of: Conference on the Fine Structure of Cells, 1171
- Biological Specimens: Estimation of Zinc in—Decommation of Zinc-65 (T. E. Banks, R. Tupper, R. W. E. Watts and Prof. A. Wormald), 348
- Separation of Radioactive Zinc from Cyclotron-Irradiated Copper (R. Tupper and R. W. E. Watts), 349
- Biological Specification and Biological Standards in the British Pharmacopoeia, 1953 (Prof. A. A. Miles), 433
- Biological Standards in the British Pharmacopoeia, 1953: Biological Specification and (Prof. A. A. Miles), 433
- Biological, Agricultural and Medical Research: Statistical Tables for (Sir Ronald A. Fisher and Dr. Frank Yates), fourth edition, review by Prof. J. H. Gaddum, 183
- Biologically Active Polypeptides from *Mikto aspid*: Hypoglycin A, B—(Prof. C. H. Hemmell, K. Rayle and Dr. P. Feigl), 356
- Biologists: The Training of (Institute of Biology Discussion on), 291, 897

- Biologists (Applied), Association of: Symposium on the Potato Root
Eelworm, 295
- Jubilee Conference, 1125
- Biology: The Electron Microscope In (Dr. Ralph W. G. Wyckoff), 419
- Marine, In Natal (Robert Clarke), 1164
- New, No. 16 (edited by M. L. Johnson, Michael Abercrombie and
G. E. Fogg), review by T. H. Hawkins, 1109
- Quantitative (Cold Spring Harbor ninetieth Symposium on), (The
Mammalian Focus—Physiological Aspects of Development), 430
- Biology, Institute of: Booklet on Biology as a Career, 63
- Discussion on the Training of Biologists, 291, 997

Cassini, R., and Carabelli, E.: Seismic Problems in Exploration Geophysics, 246

- Campopela**: Intensities of Discrete Radio Sources in Cygnus and, at 22.6 Mc/s. (J. S. Hay and V. A. Hughes), 819
- Carr Iron (Gray)**: Graphite Lubrication In (Prof. E. Knuth-Winterfeldt and E. Langer), 497
- Casy, A. P.** (Beckett, A. H., and) : Stereochemistry of certain Analgesics, 1231
- Cat**: Light Absorption In the Crystalline Lens of the (R. A. Weale), 1049
- Cat Embryos**: Detection of the Sex of, from Nuclear Morphology In the Embryonic Membrane (Margaret A. Graham), 310
- Catalase**: Reactions of Methaemoglobin and, with Peroxides and Hydrogen Donors (Prof. D. Keilin and Dr. E. F. Hartree), 720
- Catalyst** In the Decomposition of Carbon Monoxide in presence of Iron: Nature of the (Dr. B. Chatterjee and P. P. Das), 1046
- Cathart, Prof. E. P.**: Death of, 476; obituary by Prof. R. C. Garry, 522
- Cathodes**: Oxide-coated (Société Française des Ingénieurs Techniciens du Vide International Convention on), 896
- Cation Analysis of Woods Hole Sea Water** (D. R. Shanklin), 82
- Cation-Exchange Resins**: Influence of, on Adenosine Triphosphate (N. A. Lund, P. S. M. Grylle and J. S. Harrison), 544
- Cationic Polymerization and related Complexes** (edited by Dr. P. H. Plesch), review by Dr. N. Grassie, 918
- Caton-Thompson, Miss Gertrude**: Honorary degree of Litt.D. of the University of Cambridge conferred on, 1171
- Cattle**: Sameal Diluents in the Artificial Insemination of (R. C. Campbell and J. Edwards), 637
- Cattle (Dairy)**: Rate of Milk Secretion In, in the Intervals between Consecutive Milkings (G. L. Bailey, P. A. Clough and F. H. Dodd), 404
- Cattle (Domestic)**: Play In, In Britain—an Analysis of its Nature (A. Brownlee), 1081
- Cauliflower Leaves**: Relation of Molybdenum Status and Nitrogen Supply to Respiration In (Dr. G. Ducat and Dr. E. J. Hewitt), 1141
- Caunt, A. D.** et autres (établi par): Tables de Constantes et données numériques, Vol. 5, constantes sélectionnées; Atlas des longueurs d'onde caractéristiques des bandes d'émission et d'absorption des molécules diatomiques, review by Dr. A. G. Gaydon, 417
- Cause of Dormiency in Leaves**: Experiments on the (R. Snow and Mary Snow), 644
- Causes of War**: Removing the (Dr. Kathleen Lonsdale), review by R. B., 8
- Caval Sphincter In *Phoca vitulina* L.** (R. J. Harrison, J. D. W. Tomlinson and L. Bernstein), 86
- Cavallaro, Prof. C.** and others: Diabetogenic Action of Pancreatic Glucagon, 585
- Cavanagh, Dr. J. B.** and Thompson, Prof. R. H. S.: Reactions of the Human Body to Injury, 1173
- Cave, Marion S.** and others: Plant Genera, their Nature and Definition, review by Dr. W. B. Turfill, 908
- Caving**: British (edited by C. H. D. Cullingford), review by Miss M. M. Sweeting, 843
- Cazaud, R.**: Fats of Metals, translated by A. J. Fender, review by Prof. P. C. Thompson, 1011
- Cell**: Pathology of the (Prof. Gordon Roy Cameron), review by Dr. E. S. Horning, 905
- Cell Biology**, International Society for: Eighth Congress, 1171
- Cell Physiology**, review by Dr. E. S. Horning, 905
- Cell Wall of *Coccidioides immitis***: Chemical Composition of the (Dr. F. Blank and Ruth C. Burke), 829
- Cell Wall of *Yarrowia***: Structure of (Prof. R. D. Preston and Prof. W. T. Azbury), 203; (Prof. F. C. Steward and Prof. K. Mablethaler), 204
- Cellulose**: Synthesis of Oligosaccharides during Enzymatic Hydrolysis of, by *Aspergillus flavus* (Prof. K. V. Giri, V. N. Nigam and K. S. Srinivasan), 953
- Cells**: Fine Structure of (International Union of Biological Sciences Conference on), 1171
- Cells (Animal)**: A Quantitative Method for Growing, *In vitro* (Dr. L. M. Rinaldu), 1134
- Cells (Disrupted Staphylococcal)**: Effect of Nucleic Acids on Protein Synthesis and Amino-Acid Incorporation in (Dr. E. F. Gale and Joan P. Folkes), 1223
- Cells (Exocrine and Endocrine)**: Chemical Composition of the Golgi Apparatus in the, in the Pancreas of the Mouse (Dennis Lacy), 1235
- Cells (Growing Rod)**: Potassium Absorption by (R. Brown and P. M. Cartwright), 192
- Cells (Human Red)**: Phosphate Partition and Turnover in (Dr. T. A. J. Prankerd and Dr. K. L. Altman), 870
- Cells (Individual)**: A Technique for combining the Staining of Fixed Nuclear Material with the Subsequent Separation of Plant Tissue Into (B. J. Harris and Prof. G. E. Blackman), 642
- Cells (Red)**: Physical Instability and Thermal Shock in (Dr. J. E. Lovelock), 659
- Cells (Root)**: Protein in Developing (C. Morgan and W. S. Reith), 1074
- Cells (Stomatal)**: Chlorophyll Content and Carbon Dioxide Uptake of (Dr. M. Shaw and G. A. MacLachlan), 29
- Cells (Stomatal Guard)**: Chlorophyll and Photosynthesis In (Dr. E. W. Yemm and Dr. A. J. Willis), 726
- Cellulose**: Recent Advances in the Chemistry and Industrial Applications of (Scottish Sections of the Royal Institute of Chemistry Symposium on), 111, 894
- Cellulose in Air**: Detection of Free Hydroxyl Radicals during the Oxidation of (R. Holden), 539
- Cellulose Chemistry and the Textile Industry** (Dr. D. A. Clibbens), 245
- Celluloses (Native and Mercarized)**: Structures of (Dr. M. K. Sen and Dr. S. C. Roy), 298
- Cement and Concrete Association**: Gift of £500 to the Department of Civil Engineering, University of Leeds, for scholarships, 570
- Census 1951, England and Wales**: County Register, London (General Register Office), 480
- Census of Agriculture in Iraq** (Dr. K. G. Fazeloo), 1029
- Censuses and Surveys**: Sampling Methods for (Frank Yates), second edition, review by Dr. J. Wishart, 936
- Centenaries in 1954**: Scientific (Joan M. Eyles), 9
- Central Africa**: University Education In, 1007
- Central American Orchids**, review by V. S. Summerhayes, 181
- Centre National de la Recherche Scientifique**: Scholarships to British workers in Medical Science offered by the Medical Research Council on behalf of the, 339
- Cephalaspids (Spratzen)**: Morphologic and Systematic Studies of (Gustav Wünnig), 713
- Ceramics**: Reduction in the Loss Factor of certain, by Heat Treatment (H. Rawson), 447
- Cerastium arcticum**, Lange (Nicholas Potunin), 89; (Olive E. Brett), 89
- Cercospora musae** Zimm. in Pure Culture: Controlled Sporulation of (Lucas Calpouzos), 1084
- Cerebrospinal Fluid**: Cortisone and Hydrocortisone In (Dr. D. N. Baron and Dr. Denis Abelson), 174
- Cestode**: Anti *Myrmica rubra* L. and *M. scabrinodis* Nylander as Intermediate Hosts of a (D. A. Muir), 688
- Chadwick, Sir David**: Obituary by Sir Alan Green, 977
- Chadwick, Sir James**: Radioactivity and Radioactive Substances, fourth edition, review by S. Wentroub, 933
- Chadwick, S. C.** and Neale, Dr. S. M.: Conductivities of Polyelectrolyte Solutions at High Frequencies, 493
- Chaffinch**: The Process of Song-Learning In the, as studied by means of the Sound Spectrograph (Dr. W. H. Thorpe), 463
- Chain, Prof. E. B.**: Honorary fellowship of the Weizmann Institute of Science conferred on, 67
- To be presented with the Paul Ehrlich and Ludwig Darmstaedter Prize of the Ehrlich Institute, Frankfurt am Main, 151
- The Development of Antibiotic Chemotherapy, 151
- Chakravarti, S. C.**: Anatomy of Roots and Shoots of *Brassica campestris* L. in relation to Vernalization, 407
- Chalk River**: Life at (Freda Kinsey), 18; (Dr. W. B. Lewis), 619
- Chalklin, Prof. F. C.**: Obituary by Prof. H. S. W. Massey, 708
- Challenger Society**: Grants in aid of research in Marine Biology or Oceanography, 1026
- Challinor, Dr. C. E.**: Electron Microscopy Group of the Institute of Physics—Annual Conference, 340
- Chalvet, M.**: Engineering Dimensional Metrology, 293
- Chambers, H. H.**: Gas Absorption, 1029
- Chambers, J.**: Heat Therapy of Virus-infected Raspberries, 595
- Chambers, P. C.**: Appointed director of agriculture, Northern Region, Nigeria, 570

- Coconut : Development of the Syncytial Endosperm of (Prof. Victor M. Cutler, Jun., and Bonnie Freeman), 827

- Cod : Parasites of the, *review* by Dr. G. Lapage, 1157
 Cod (Salt) : Brownish-yellow Discoloration of, and Halophile Calcium-needing Micro-organisms (Pall Orlaen), 1143
 Cod Fillets : Deoxyribonucleic Acid in the Expressible Fluid of (R. M. Lova), 544
 Coddington, E. A., and others : Contributions to the Theory of Nonlinear Oscillations, Vol. 2 (edited by S. Lefschetz), *review*, 635
 Coenzyme of Kidney Phosphatase (Prof. M. Lora-Tamayo and Eldiberto F. Alvarez), 548
 Coffey, George L., and others : Azaserine, a New Tumour-Inhibitory Substance—Antibiotic Studies of Azaserine, 72
 Cohen, Prof. John : New Pathways to Piano Technique, *review*, 373
 Cohen, Prof. John, and others : Natural History of Learned and Scientific Societies, 328, 714
 Cohen, R. D. (Rushton, Dr. W. A. H., and) : Visual Purple Level and the Course of Dark Adaptation, 301
 Cohn, Prof. Edwin J. : Obituary by Dr. John T. Edall, 104
 Cohn, Mildred, and Townesend, Jonathan : A Study of Manganous Complexes by Paramagnetic Resonance Absorption, 1090
 Coldough, Dr. T. P. : Awarded the Bessemer Gold Medal for 1954 of the Iron and Steel Institute, 852
 Cold : Rapidity of Thyroid Reaction to (Dr. Estanislao Del Conte and Marie Stux), 83
 Cold Spring Harbor Symposium on Quantitative Biology, 19, The Mammalian Foetus—Physiological Aspects of Development, 430
 Cold-worked Copper at Low Temperature : Thermoelectric Power of (Prof. M. J. Druryevsky and K. J. Blok van Laar), 591
 Cole, R. David, and others : Inhibition of Mammary Tumours during Lactation Induced in Virgin Mice, 1035
 Cole, William E. (edited by) : Some Conjugated Proteins, a Symposium (Six lectures presented at the Ninth Annual Conference on Protein Metabolism held at the Bureau of Biological Research, Rutgers University, State University of New Jersey, January 30-31, 1953), *review*, 141
 Coles, R., and Underwood, J. R. : Hatchability of Hen Eggs and Lymphomata, 877
 Colhoun, E. H. : Temperature Acclimatization in Insects, 582
 Collagen : Soluble (Research Panel of the British Gelatine and Glue Research Association Symposium on), 342
 Colledan, V., and Salem, A. M. : Seismic Problems in Exploration Geophysics, 246
 Colledge, R. (Tyrrell, H. J. V., and) : Thermal Diffusion Potentials and the Soret Effect, 264
 Colleges in the United States : Establishment of an Advisory Committee on Government Support of Universities and (National Science Foundation, Washington), 108
 Collier, Dr. H. O. J. : Recent Advances in the Chemistry and Biology of the Pteridines, 1177
 Collingwood, Dr. E. F. : Elected a Fellow of the Royal Society of Edinburgh, 474
 Collins, Dr. D. H. : Appointed to the chair of pathology in the University of Sheffield, 663 ; work of, 663
 Collits, E. : Appointed government chemist, Medical Department, Hong Kong, 194
 Collits, Dr. S. F. : Awarded a Leverhulme Research Grant, 1025
 Colloquial and Dialect Rock Terms : Glossary of, *review* by V. A. Eyles, 7
 Colombo Plan for South and South-East Asia—Interim Report, 715
 Colonial Agriculture, Animal Health and Forestry Research : Report of the Committee for, 374
 Colonial Development—Main-power and Finance, 47
 Colonial Economic Research Committee : Report of the, 374
 Colonial Fisheries Advisory Committee : Report of the, 374
 Colonial Insecticides Committee : Report of the, 374
 Colonial Medical Research Committee : Report of the, 374
 Colonial Microbiological Research Institute : Appointment of W. G. C. Forsyth as principal scientific officer, 112
 Colonial Office : Fishery Publications, Vol. 1, No. 3, Report on the Mauritius—Seychelles Fisheries Survey, 1948-1949 (Dr. J. P. G. Wheeler and Dr. P. D. Ormsman), 186
 Colonial Research 1952-1953, 374
 Colonial Products Research Council : Report of the, 374
 Colonial Relations in the British Commonwealth (H. Hopkinson), 737
 Colonial Research 1952-1953 (Colonial Office), 374
 Colonial Research Council : Report of the, 374
 Colonial Service : Recast Appointments and Promotions, 112, 194, 570, 760, 896, 981, 1171
 Colonial Social Science Research Council : Report of the, 374
 Colorado School of Mines : Offer of a Tuition Scholarship, 526
 Colomestic Chemical Analytical Methods for Industrial, Research and Clinical Laboratories developed for use with the Lovibond Comparator : A Handbook of (Tintometer, Ltd.), *review* by J. King, 607
 Colour Reagents for Amino-Acids : Aromatic Aldehydes as Specific Chromatographic (G. Curzon and J. Giltrow), 314
 Colour-rendering Properties of Fluorescent Lamps (Colour Group of the Physical Society Symposium on), 100
 Colours (Structural) : Animal Biochromes and (Dr. Denis L. Fox), *review* by Dr. E. F. Hartree, 909
 Coleky, Dr. J. : Recent Advances in the Chemistry and Biology of the Pteridines, 1178
 Columbia University : The Bicentenary of (Prof. L. C. Dunn), 703
 Columbian Oxide Bands : Rotational Analysis of the (K. Suryanarayana Rao), 1240
 Colwyn Medal of the Institution of the Rubber Industry awarded to Dr. D. Parkinson, 62
 Comber, Prof. Norman M. : Obituary by J. S. Wilcox, 189
 Comets : The Accretionary Origin of, *review* by Prof. W. M. H. Greaves, 415
 Comets and their Origin (Dr. R. A. Lytle), *review* by Prof. W. M. H. Greaves, 415
 Comité International de Photobiologie : International Congress, 430, 1075
 Commemorative Medal of Prince Albert I of Monaco (Prof. Stanley-Bendall) for 1954 awarded to Captain de Corvette G. Houot and Engineer Officer P. Willis, 1217
 Commover, Prof. Barry : Awarded the Newcomb Cleveland Prize of the American Association for the Advancement of Science, 336 ; work of, 336
 Commonwealth : The Yearbook of the Universities of the, 1954 (edited by Dr. J. F. Foster), *review*, 1205
 Commonwealth (British) : Colonial Relations in the (H. Hopkinson), 737
 Commonwealth Agricultural Bureaux : Election of W. F. C. Morton as chairman, 714
 Commonwealth Bureau of Animal Breeding and Genetics : Technical Communication No. 5, Generation Periods (compiled by J. H. Keaneth, with additions by G. R. Ritchie), third edition, *review*, 327
 Commonwealth Countries : Bursaries for research in (Royal Society and the Nuffield Foundation), 151
 Commonwealth Exhibitions : Research Studentships and (Trinity College, Cambridge), 195
 Commonwealth Fund : Fellowship Awards, 526, 714
 Commonwealth Fund of New York : Report for the Year 1952-53, 576
 Commonwealth Institute of Entomology : Sixth Commonwealth Entomological Conference, 429
 Commonwealth Observatory, Canberra : Report of the Commonwealth Astronomer for the Year 1952, 160
 Commonwealth Scientific Office (British), North America : BCSO Review of Science in the U.S.A. for the Year ending June 1953, 900
 Commonwealth Scientific and Industrial Research Organization, Australia : Bulletin No. 272, Standardized Plant Names in Australia, revised version, 805
 Section of Mathematical Statistics to become the Division of Mathematical Statistics, with headquarters in Adelaide, 807
 New Tribophysical Laboratory of the (Dr. W. Bose), 969
 Reassignment of Dr. L. B. Bull as chief of the Division of Animal Health and Production, 1123
 Appointment of D. A. Gill as chief of the Division of Animal Health and Production, 1123
 Commonwealth Scientific and Industrial Research Organization, and others : Australian and United Kingdom Postgraduate Research Studentships tenable in Australia, 429
 Comparator (Lovibond) : A Handbook of Colorimetric Chemical Analytical Methods for Industrial, Research and Clinical Laboratories developed for use with the (Tintometer, Ltd.), *review* by J. King, 607
 Competitive Method of Determining Association Constants (R. Foster), 222
 Complex Analysis, an Introduction to the Theory of Analytic Functions of One Complex Variable (Prof. Lars V. Ahlfors), *review*, 558
 Composite Wood, Vol. 1, No. 1, 428
 Composition of Bone and Muscle from the Lordotic and Normal Guppy, *Lebistes reticulatus* (Dr. Harold L. Rosenthal), 693
 Composition of Pentose Nucleic Acids : Regularities in the (Dr. David Elson and Prof. Erwin Chargaff), 1037
 Compounded $Mg_2Cr_2Al_2$ (Intermetallic) : Crystal Structure of the (Stan Semson), 1185
 Compounds : Five-Membered Heterocyclic, with Nitrogen and Sulfur or Nitrogen, Sulfur and Oxygen (except Thiazole), (L. L. Bamber), *review* by Dr. L. D. Loudon, 930
 Compounds (Carbon) : Chemistry of (edited by Dr. E. H. Rodd), Vol. 1, Part B, Aliphatic Compounds, *review*, 231 ; Vol. 2, Part A, Aliphatic Compounds, *review* by Dr. C. Buchanan, 931
 Compounds (Carbonyl) : A Rapid Gasometric Method of Analysis for "Reducing" Sugars and other (Dr. Philip S. Skell and Joseph G. Crick), 401
 Compounds (Optically Active) : Structure of, in the Solid State (Prof. J. M. Bijvoet), 888
 Compounds (Organic) : Estimation of (Dr. P. Wild), *review* by B. A. Ellis, 929
 Steric Effects in the Electronic Spectra of (Dr. E. A. Braude, Dr. F. Sondheimer and Dr. W. F. Forbes), 117, *errata*, 195
 Compounds of Carbon : Organic Chemistry, the Chemistry of the (Prof. Lucius Junius Dehaas), second edition, *review* by G. F., 183
 Compression (Rapid) : Ignition of Methane-Air Mixtures by (Ni P. W. Moore and J. R. Simonsen), 543
 Compton Energy—Angle and the Klein-Nishina Formula : Graphs of the (Ann T. Nelms), 665
 Computer Conference (Western) : Analogue and Digital Computers—Proceedings of the, 200
 Computers : Analogue and Digital—Proceedings of the Western Computer Conference, 200
 Computing Machinery, Association for, and others : Proceedings of the Western Computer Conference held by the joint IRE-AIEE-ACM Computer Conference Committee, Los Angeles, 200
 Computing Machines (Automatic Digital) : Summer School in Programme Design for (University Mathematical Laboratory, Cambridge), 981
 Cones, Dr. J., and Gros, Ch. M. : Influence of the Thyroid upon the Survival-rate of Guinea Pigs treated with X-Rays, 307
 Concorde Prize of the National Academy of Sciences, Washington, presented to Dr. William Shockley, 1172
 Concrete Technology : Scholarships in Gift of £200 a year for seven years from Wm. Aurrey and Son (Leeds), Ltd., to the University of Leeds for, 570
 Coody, William : The Poetics in Wales, 1130
 Conductivities of Polyelectrolyte Solutions at High Frequencies (S. C. Chadwick and Dr. S. M. Neale), 493
 Conductivity Induced in Insulating Materials by X-Rays (J. F. Fowler and Dr. F. T. Farmer), 317
 Conductivity Measurements on Inert Media using Internal Calorimetry : Thermal (A. L. Haug), 493
 Conductometric Detection of Ions in Paper Chromatograms (G. de Vries), 735
 Configuration (Absolute) : Determination of, by Laws Photographs (Dr. H. Judith Greenfield-Wells and Prof. Kathleen Lonsdale), 1145
 Configuration of Cholesterol : Absolute (Dr. J. W. Cornforth, Irene Yocobosky and Dr. G. Popplik), 536
 Configurations (Tetrahedral Pyramidal) : Metal-Oxygen Bonds, and Co-ordination Complexes with (Dr. George Philip and D. H. Irvine), 1148
 Conflict between Science and Religion : Some Aspects of the (Prof. H. Price), 152
 Congo (Belgian) : Boron Deficiency in Oil Palms in the Kasai Region of the (J. D. Farver), 1097
 Flora of the, 854

- Congo Belge et du Ruanda-Urundi: Flore du, Vol. 4, Spermatophytes, Papilionaceae, 654
- Coniferous Petrified Forest in Patagonia (Mary Gordon Calder), 243

 Egerton, Sir Alfred, and others: Effect of Hydrogen Peroxide on the Analysis of Organic Peroxides, 399
 Eggs (Hae): Hatchability of, and Lymphomatosis (R. Coles and J. R. Underwood), 877
 Eggs (Unfertilized Rat): Nuclear Formation and Cleavage Induced in (C. R. Austin and A. W. H. Braden), 999
 Egypt: Cotton Yields in, *review* by Prof. S. C. Harland, 6
 Egyptian Scorpion and Cobra Venoms: Influence of, on Mammalian Erythrocytes *in vitro* (Dr. A. H. Mohammed, H. Robayem and O. Zakly), 170
 Ehrenberg, Dr. Lars, and Anderson, Dr. Göran: Probable Side-effect of Nuclear Reactions in the Biological Action of Fast Protons, 1086
 Ehrlich, John, and others: Azaserine, a New Tumour-Inhibitory Substance—Antibiotic Studies of Azaserine, 72
 Ehrlich (Paul) Institute, Frankfurt am Main: Celebration of the hundredth anniversary of the birthday of Paul Ehrlich and of Emil von Behring, 151
 Paul Ehrlich and Ludwig Darmstadter Prize to be presented to Prof. E. B. Chain, 151
 Ehrlich (Paul) and Ludwig Darmstadter Prize of the Ehrlich Institute to be presented to Prof. E. B. Chain, 151
 Elgee, M.: Fast Chemical Reactions, 1163
 Ellenberg, Samuel, and Steenrod, Norman: Foundations of Algebraic Topology, *review* by Dr. R. G. Cooke, 934
 Elstaka, Prof. Albert: Seventy-fifth birthday celebrations (American Association of Scientific Workers), 430
 Einstein, Prof. Albert, and others: Scientific Papers presented to Max Born on his retirement from the Tait Chair of Natural Philosophy in the University of Edinburgh, *review* by D.R.H., 327
 Einstein Award of the Lewis and Ross Strauss Memorial Fund awarded to Dr. Richard Phillips Feynman, 524
 Einstein Relation Relative Viscosity and Volume Concentration of Suspensions of Spheres (A. J. Hughes), 1089; (Donald R. Oliver and Prof. Stacey G. Ward), 1090
 Eisele, P., and others: Vibrations as a Cause of Disintegration in Liquid Sheets, 495
 Ely-Poulson, P.: Experimentally produced 'Polyagglutinability' (T-Transformation of Erythrocytes *in vivo*) in Guinea Pigs Infected with Pneumococci, 82
 Ejection of Very Fast Particles from the Sun: Radio Evidence of the (J. P. Wild, J. A. Roberts and J. D. Murray), 532
 Eklund, M. G., and others: Data for X-Ray Analysis, Vol. 2, Tables for Computing the Lattice Constant of Cubic Crystals, *review* by I. G. Edmunds, 931
 Elbo, J. G. R.: Obituary, 803
 Elder, Carole C., and others: Azaserine, a New Tumour-Inhibitory Substance—Isolation and Characterization of Azaserine, 72
 Elderton, Dr. E. M.: Obituary by Dr. F. N. David, 1211
 Eldridge, R. H.: Appointed meteorologist, Gold Coast, 981
 Election to the Royal Society: Age of (Prof. A. V. Hill), 758
 Electric Soldering Iron: Production of an (Kenroy, Ltd.), 153
 Electrical Breakdown of Gases (Prof. J. M. Meek and Dr. J. D. Crags), *review* by Dr. S. Whitehead, 920
 Electrical Conductivity of the Perylene-Bromine Complex (Hideo Akamatsu, Hiroo Inokuchi and Yoshio Matsunaga), 168
 Electrical Effect in Liquid Crystalline Solutions containing Amphiphilic Salts (Dr. P. A. Winsor), 81
 Electrical Engineering in Nottingham, 1122
 Electrical Engineering in the University of Wales, 852
 Electrical Engineers, Institution of: Election of Ernest Leese to honorary membership, 107
 Faraday Medal awarded to Isaac Shoenberg, 107
 Presidential Address (H. Bishop), 248
 Electrical Method of Determining the Sex of Sea Urchins (Ethel Browne Harvey), 86
 Electrical Processes in Gases: High-Energy Accelerators, Cosmic Rays and—Dublin Meeting of the Physical Society (Dr. T. E. Nevill), 1127
 Electrically Heated Filament: Temperature Distribution in an (Sir K. S. Krishnan and S. C. Jain), 820
 Electricity: A History of the Theories of Aether and (Sir Edmund Whittaker), *review* by Dr. R. Hagedorn, 838
 Electrification of Petrols: Static (E. W. B. Gill), 398
 Electrodeposition and Metal Finishing: Fourth International Conference on (Institute of Metal Finishing), 365
 Electrodynamics (Arnold Sommerfeld), translated by Edward G. Ramberg, *review*, 747
 Electrolytic Corrosion of Iron and Copper (W. F. Higgins), 994
 Electromagnetic Field: Application of the Hall Effect in a Semiconductor to the Measurement of Power in an (Prof. H. M. Barlow), 41
 Electromagnetic Waves emitted on Detonation of Explosives (H. Kolsky), 77
 Electron Diffraction (Prof. Z. G. Pinsker), translated by J. A. Spink and E. Felt, *review* by Dr. H. Lipson, 919
 Electron Energy Distribution in the Striated Hydrogen Discharge (Dr. R. L. F. Boyd and N. D. Twiddy), 633
 Electron Micrographs of Thin Tissue Sections: High Resolution (T. H. Flewett and Dr. G. Erve), 309
 Electron Microscope: Annual Summer Laboratory Course in Techniques and Applications of the (Cornell University), 667
 Electron Microscope in Biology (Dr. Ralph W. G. Wyckoff), 419
 Electron Microscopic Observations on Bacterial Nuclei (Dr. J. R. G. Bradfield), 184
 Electron Microscopy: International Conference on (Joint Commission on Electron Microscopy of the International Council of Scientific Unions), 194, 291
 Electron Optics (Prof. O. Klemperer), second edition, *review* by Dr. L. Jacob, 182
 Electron Optics, Pure and Applied, *review* by Dr. L. Jacob, 182
 Electron Resonance in Ionomorphic Waxes (C. O. Hines), 1087
 Electron Structures of Organic Molecules (Prof. Lloyd N. Ferguson), *review* by Dr. J. C. Speakman, 917
 Electronic Impact: Influence of, on the Rate of Sorption of Gases on to Getter Materials (Dr. S. Wagnier), 684
 Electronic Instruments: Design, Use and Maintenance of (Specialized Course at the Isotope School, Atomic Energy Research Establishment), 292
 Electronic Spectra of Organic Compounds: Steric Effects in the (Dr. E. A. Braude, Dr. F. Sondheimer and Dr. W. F. Forbes), 117, *errata*, 195
 Electronic Theory of Valency in Organic Chemistry, *review* by Dr. J. C. Speakman, 917
 Electronics, Institution of (North-West Branch): Ninth Annual Exhibition, 1170
 Electrons (K-Conversion): Angular Correlations between (Dr. A. L. Breitenberger), 737
 Electrons in Metals, *review* by Dr. E. P. Wohlfarth, 923
 Electrons and Holes across a Twin Boundary in Germanium: Transmission of (Dr. E. Billig and M. S. Ridout), 496
 Electrophoresis (Paper): Photoelectric Scanners for use in (Evans Electroscintulum, Ltd.), 1215; (Joyce, Loeb and Co., Ltd.), 1215
 Electrophoresis of Group-Specific Extracts of Streptococci (Dr. N. J. Berridge and C. A. E. Briggs), 486
 Electrophoresis of Muscle Extracts: Zono-Separation of Phosphocreatine, Creatine, Beta-Alanine Peptides, and Nucleotides (Dr. Albert Wollenberger), 205
 Electrophoresis of the Oligosaccharides synthesized from Sucrose by Yeast Invertase: Paper (Dr. D. Gross), 487
 Electrophoresis and Gel Strength (D. A. L. Goring), 724
 Electrophoretic Behaviour of Hyaluronidase (Antonio Caputo), 358
 Electrophoretic Separation on Filter Paper of the Soluble Liver-Cell Proteins of the Rat using Borate Buffer (G. Adjutant), 539
 Electrostatique et magnétostatique (Emile Durand), *review* by Prof. L. Rosenfeld, 933
 Element 99, 290
 Element 100: Production of (Prof. G. T. Seaborg and collaborators), 757
 Elements: The Oxidation States of the, and their Potentials in Aqueous Solutions (Prof. Wendell M. Latimer), second edition, *review* by G. Fowles, 928
 Photoconductivity in the (Dr. Trevor Simpson Moss), *review* by A. H., 232
 Elevated Temperatures: Radiation-suppressing Coatings for Metals at (Dr. A. H. Sully, E. A. Brandes and R. B. Waterhouse), 1074
 Eley, Dr. D. D.: Appointed to the chair of physical chemistry in the University of Nottingham, 62; work of, 62
 Elimination of the Fluorescence of Estrogens in Urinary Extracts by Hydrogen Peroxide (C. Heughebaert), 1043
 Elton, Dr. G. B.: Recent Advances in the Chemistry and Biology of the Parklins, 1176
 Eley, Dr. C.: The Potato Root Eelworm and its Control, 296

 Everatt, Dr. A. J. and others : Effect of Hydrogen Peroxide on the Analysis of Organic Peroxides, 399
 Everatt, Prof. D. H. : Appointed to the Leverhulme chair of physical and inorganic chemistry in the University of Bristol, 523 ; work of, 523
 Evlson, Dr. F. F. : Early Arrivals in Salinic Prospecting, 1047
 Evolution : The Major Features of (Dr. George Gaylord Simpson), review by Dr. G. R. de Beer, 1107
 A Modern View of, review by Dr. G. R. de Beer, 1107
 Evolution in Action (Dr. Julian Huxley), review by Prof. J. Gray, 227
 Evolution of the Human Mind, review by Dr. J. S. Weiner, 839
 Evolution and Epistemology (Prof. C. H. Waddington), 880
 Ewe : Relationship of Oestrogen and Progesterone to Oestrous Behaviour of the (Dr. T. J. Robinson), 678
 Ewes : Progesterone Secretion in (D. G. Edgar), 639
 Ewing, Prof. A. W. G. : Speech for Deaf Children, 244
 Ewing, Irene R., and Ewing, Prof. A. W. G. : Speech and the Deaf Child, review by R. Askew, 967
 Ewing, M., and others : Trans-Atlantic Profile of Total Magnetic Intensity and Topography, from Delour to Barbados, 528
 Exact Science : The Development of Meteorology as an (Dr. O. G. Sutton), 1112
 Exchange of Bone Calcium and Phosphorus *in vivo* (T. G. Taylor, Dr. J. H. Moore and Dr. D. H. Tomlin), 1137
 Exchange of Students for Technical Experience, International Association for the : Sixth Annual Report, 111
 Experiments with Heavy Water : Chemical Primary Processes in the Action of Ionizing Radiations in Water—Evidence from (Patrick Kelly, Dr. Tron Rigg and Dr. Joseph Weiss), 1130
 Excluded Roots : Growth of (J. C. Skinner and Dr. H. E. Street), 1214
 Excluded Tomato Roots : Effects of α -(1-Naphthyl-methylsulphide)-Propionic Acid on the Growth of (Dr. H. E. Street), 253
 Excitation of Mercury Vapour by Positive Ion Impact : Ionization and (Prof. R. M. Chaudhuri, C. M. Aslam and S. U. Hasan), 1186
 Excited Nucleons (Prof. C. P. Powell), 469
 Exhibition of 1951, Royal Commission for the : Awards for 1954, 1216
 Exhibitions (Commonwealth) : Research Studentships and (Trinity College, Cambridge), 195
 Existence of Two Types of Ribonucleic Acid : Evidence for the (Dr. Roy Markham, Dr. R. E. F. Matthews and Dr. J. D. Smith), 537
 Exocrine and Endocrine Cells in the Pancreas of the Mouse : Chemical Composition of the Golgi Apparatus in the (Dennis Lacy), 1235
 Experimental Anthrax : Observations on—Demonstration of a Specific Lethal Factor produced *in vivo* by *Bacillus anthracis* (H. Smith and J. Kappes), 869
 Experimental Demonstrations of Balance in Populations (Dr. A. J. Nicholson), 862
 Experimental Induction of Buds from Fern Leaf Primordia (Elizabeth G. Cutter), 440
 Experimental Production of Identical Twins in Rabbits : Attempted (M. Brodbeck), 160
 Experimental Science : Robert Grosscote and the Origins of, 1100-1700 (A. C. Crombie), review by Prof. E. J. Dijksterhuis, 138
 Experimental Study of Speech (Dr. B. D. Fry), 844
 Experimental Tuberculosis : Effect of, on the Distribution of Alkaline Phosphatase in the Adrenal Cortex of the Guinea Pig (Dr. Amiya B. Kar), 210
 Experimentally produced 'Polyagglutinability' (T-Transformation of Erythrocytes *in vitro*) in Guinea pigs infected with Pneumococci (P. Eijby-Poulsen), 82
 Experiments for Development Research : Statistical Design and Analysis of (Donald Sattler Villars), review by M. R. Sampford, 327
 Excluded Berley Roots : Fixation of Carbon Dioxide by (L. W. Poel), 63
 Experiments in Practical Physics : Advanced (J. E. Calthrop), second edition, reviewed by Dr. J. A. Pryde, review, 418
 Exploration Geophysicists, European Association of : Meeting in Milan (T. C. Richards), 246
 Explorations in Science (Václav Kramplert), 1199
 Explosives : Electromagnetic Waves emitted on Detonation of (H. Kolisky), 77
 Explosives (Liquid) : Suppression of Bubble Initiation of (Elwyn Jones), 77
 Exposition : Scientific Research and, 1199
 Expressible Fluid of Cod Fillets : Deoxyribose Nucleic Acid in the (R. M. Love), 544
 Extract of *Adiantum vesica* : Antitubercular Effect of an (K. C. Gupta and I. C. Chopra), 1194
 Eye of Science : From Magnifying Glass to (National Museum for the History of Science, Leyden, Exhibition), 1171
 Eyepiece (Kellner) : Photomicrography with a (Dr. Frank Smithson), 1047
 Eyles, Joan M. : Scientific Centenaries in 1954, 9

- Implantation: Delayed, in the Harbour Seal, *Phoca vitulina* L. (H. D. Fisher), 679
- In vitro Cultivation of Mouse Ascites Tumour Cells for Virus-Host Cell Studies (Dr. Benjamin V. Sigel), 584
- Inagami, Kaoru, and others: Abnormal Accumulation of 3-Hydroxykynurenine in the Mutant 'Aka-Aka' of Silkworm, 586
- Inbred Strains: Are suitable for Bio-assay? (Anne McLaren and Donald Michie), 696
- Inbred Strains of Mice: Variation within (Dr. H. Grunberg), 674
- Ince, Sir Godfrey: Industrial Relations and Human Relations, 645
- Incomplete Influenza Virus: Artificial Production of (Dr. S. Fazekas de St. Groch and Doris M. Graham), 637
- Incorporation of B-Azoxynine Into Nucleic Acids (Dr. Ise Lashitzki, Dr. R. E. F. Matthews and Dr. J. D. Smith), 346
- Independent Research Institution, 599
- India: Dissemination of Rust Fungi in (Prof. Mehta), 665
- Geology of (D. N. Wadia), third edition, review by Dr. W. D. West, 95
- Poisonous Plants of (Sir Ram Nath Chopra, Rattan Lal Bedhiwar and Prof. Sudhanshu Ghosh), Vol. 1, review by Dr. N. L. Bor, 745
- The Wealth of Raw Materials, Vol. 3, D-E (Council of Scientific and Industrial Research, New Delhi), review by Sir John Simonson, 142
- Indian Ocean Area: Occurrence of *Puccinia polypora* Underwood in the (G. Orfan), 505
- Indian Sub-Continent: Geology of the, review by Dr. W. D. West, 95
- Individuals: Short-lived Red Cells in Normal (Robert L. Evans), 129
- Indoleacetic Acid and Sugar Absorption (Hussein Said and M. I. Naguib), 1074
- Indole-3-Acetic Acid in Laminae of *Herma brasiliensis*: Occurrence of (Dr. E. W. Boffe-Jones), 127
- Induction of Buds from Fern Leaf Primordia: Experimental (Elizabeth G. Cutter), 440
- Induction of Ovarian Tumours with 9:10-Dimethyl-1:2-Benzanthracene (June Marchant, Prof. J. W. Orr and Prof. D. L. Woodhouse), 307
- Industrial Applications of Cellulose: Chemistry and (Scottish Sections of the Royal Institute of Chemistry Symposium on), 111, 896
- Industrial Instruments: A Manual of Scientific and, review by Dr. C. A. Taylor, 464
- Industrial Materials: Microbial Spoilage In (Society for Applied Bacteriology Symposium on), 102
- Industrial Methods of Sterilization (Society for Applied Bacteriology and the Microbiology Group of the Society of Chemical Industry Symposium on), 333
- Industrial Organic Solvents: Toxicity of (Dr. Ethel Browning), revised edition, review, 655
- Industrial Psychology, National Institute of: H. M. Vernon Prize awarded to Dr. N. H. Mackworth, 292
- Industrial Relations and Human Relations (Sir Godfrey Ince), 645
- Industrial, Research and Clinical Laboratories: A Handbook of Colorimetric Chemical Analytical Methods for, developed for use with the Lovibond Comparator (Tintometer, Ltd.), review by J. King, 607
- Industries: Nationalized, and Accountability (H. Crookshank), 382
- Industry: Atmospheric Contamination in, and the Health of the Worker (British Occupational Hygiene Society Conference on), 1078
- Personnel Officers in, 193
- Provisions in the Use of Ionizing Radiations (in Ministry of Labour and National Service, Factory Department, Factory Form 324), 251
- Radioscopes in (edited by John R. Bradford), review by W. S. Eastwood, 97
- Science and—the Pattern of the Future (Sir Harold Hartley), 1126
- Science in Education and, 367
- The Scientific Study of Human Work In (Ergonomics Research Society Conference on), 983
- Utilization of Science by, 741
- Industry (British): The Need for Education In (Sir Harry Pilkington), 1073
- Industry In Britain: Scientific Research and, 787
- Industry in the Nineteenth Century: Science and (Prof. J. D. Bernal), review by R. Brightman, 139
- Industry Committee: Joint Science and (Established by the Royal Society of Arts, the British Association for the Advancement of Science, and the Nuffield Foundation), 1072
- Industry and Science, a Study of their Relationship based on a Survey of Firms in the Greater Manchester Area, 1950-1953 (Manchester Joint Research Council), 741
- Inert Media: Thermal Conductivity Measurements on, using Internal Calorimetry (A. L. Haugh), 493
- Infective Nematode Larvae Parasitic in the Horse: Second Ecdysis of (D. Rointer), 781
- Infective Paradoxes of Rift Valley Fever Virus: Different-sized (W. du T. Naudé, T. Madson and Dr. A. Polson), 1051
- Infectivity of Group G Canine Beta Haemolytic Streptococci: Interaction of the Natural Host and the Canine Hepatitis Virus on the (Dr. Nancy Laughon and Dr. N. M. Larin), 84
- Influence of Temperature and Soil Water Content on the Seedling Blight of Maize (John L. Harper), 391
- Influenza Virus (Incomplete): Artificial Production of (Dr. S. Fazekas de St. Groch and Doris M. Graham), 637
- Influenza Viruses: Genetics of Virulence in (Sir Macfarlane Burnet and Patricia E. Lind), 627
- Influenza A Virus: Lipid Content of 'Standard' and 'Incomplete' (Marianne Uhler and Prof. Sven Gard), 1041
- Information Services: Organization and Development of (Adlib Advanced Course on), 195
- Information Theory: Probability and, with Applications to Radar (P. M. Woodward), review by Dr. D. Gabor, 793
- Information Theory made Easy, review by Dr. D. Gabor, 793
- Infrared Absorption: Quantitative Evaluation of Paper Chromatograms by (Dr. J. D. S. Goulden), 646
- Infrared Dichroism of Nylon and Polyethylene Terephthalate (Richard G. Quynn and Richard Steele), 1240
- Infrared Rays: The Application of X-rays, Gamma-rays, Ultra-violet and, to the Study of Antiquities (Dr. A. A. Moss), 712
- Infrared Spectra of Fluorinated Hydrocarbons (Dr. L. J. Bellamy and R. F. Branch), 633

Mg₂CrAl₁₀: Crystal Structure of the Intermetallic Compound (Sten Samson), 1185.
Magnetic Characteristics of Rocks, review by Dr. J. M. Bruckshaw, 840.
Magnetic Drum Calculator: Description of a (Staff of the Computation Laboratory of Harvard University), review by E. N. Mutch, 935.
Magnetic Field with Straight-line Boundaries: High-order Focusing by a Uniform (Prof. E. T. S. Walton), 1147.
Magnetic Intensity and Topography, from Delmar to Barbados: Trans-Atlantic Profile of Total (B. C. Heezen, M. Ewing and E. T. Miller), 528.
Magnetic Resonance Study: A Proton, of the Hydration of Deoxyribonucleic Acid (Dr. Bertil Jacobson, Weston A. Anderson and James T. Arnold), 772.
Magnetic Surveys: Airborne (Royal Astronomical Society Geophysical Discussion on), 281.
Magnetism: Rock, and Polar Wandering (Dr. J. Hoopes), 1183.
Magnetization of Igneous and Sedimentary Rocks: Natural (Dr. D. H. Griffiths and Dr. R. F. King), 1114.
Magnetization of Rocks: Recent Developments in Great Britain in the Study of the Permanent (Discussion at the University of Birmingham), 1114.
Magneto-Resistance of Copper to 150,000 Oersted at 4.2° K. (Dr. J. L. Olsen and L. Rindner), 682.
Magnitostatische: Electrostatique et (Emile Durand), review by Prof. L. Rosenfeld, 933.
Magnifying Glass: From, to Eye of Science (National Museum for the History of Science, Leyden, Exhibition), 1171.
Maguire, Dr. M. F.: Awarded an Overseas Scholarship for 1954 by the Royal Commission for the Exhibition of 1951, 1216.
Mahood, A. R.: Appointed entomologist, Veterinary Department, Nigeria, 760.
Maier, Joseph (Rumney, Jay, and): The Science of Society, second edition, review by Prof. T. S. Simey, 702.
Malta: Influence of Temperature and Soil Water Content on the Seedling Blight of (John L. Harper), 391.
Malta Diet (High): Low Nitrate Concentration in the Breast Milk of Bantu Mothers on a (Dr. A. R. P. Walker), 405.
Malta Rust, *Puccinia polyspora*: Resistance to the (Dr. H. H. Storey and A. K. Ryland), 778.
Major, J. V.: Cosmic Radiation, 1127.
Malapragat: The Adult Female Lower Jaw from (Prof. Raymond A. Dart), 286.
Makino, Dr. Kazuaki, and others: 'Atoxo-pyrimidine', 34.
Biological Acetylation of IsoNicotinic Hydrazide, 36.
Abnormal Accumulation of 3-Hydroxyisovalryl-CoA in the Mutant 'Alca-Alca' of Silkworm, 586.
Malanda, B., and others: Diabetogenic Action of Pancreatic Glucagon, 585.
Malaya: A Revised Flora of (Prof. R. E. Holtum), Vol. 1, Orchids of Malaya, review by V. S. Summerhayes, 1202.
Malayan Forest Rats: Moonlight and the Pregnancy of (J. L. Harrison and W. van der Bijl), 1002.
Malayan Orchids, review by V. S. Summerhayes, 1202.
Malcolm, G. N.: Awarded an Overseas Scholarship for 1954 by the Royal Commission for the Exhibition of 1951, 1216.
Male Sterility, review by Dr. C. Lutwack-Mann, 909.
Maldin, Dr. A.: Awarded a National Research Council of Canada Fellowship for Medical Research, 1216.
Mallowan, Prof. M. E. L.: Archaeology of Lachish in the Near East, review, 792.
Malone, A. B.: Airborne Magnetic Surveys, 281.
Malpas, Dr. P. H. (McGeown, Mary G., and): Synthesis of Ribose in Animal Tissue, 212.
Maltose Fermentation in *Saccharomyces diastaticus*: Identification of the Genes for (R. B. Gilliland), 409.
Mammal Society of the British Isles, 980.
Election of Officers, 980.
Mammalian Erythrocytes *in vitro*: Influence of Egyptian Scorpion and Cobra Venoms on (Dr. A. H. Mohammed, H. Roheyan and O. Zaky), 170.
Mammalian Foetus—Physiological Aspects of Development (Cold Spring Harbor nineteenth Symposium on Quantitative Biology), 430.
Mammalian Growth Hormone: Influence of, on Rate of Growth of Fish (D. R. Swift), 1096.
Mammals: British, 243.
Mammals (Foetal and Neonatal): Blood-sugar in (R. F. W. Goodwin), 777.
Mammary Myoepithelium in the Rabbit: Milk Ejection resulting from Mechanical Stimulation of (B. A. Cross), 450.
Mammary Tumours: Inhibition of, during Lactation Induced in Virgin Mice (Thomas A. Deane, Lowell L. Sprick, Prof. William R. Lyons, Prof. Choh Hao Li, R. David Cole and Tetsuo Hayashida), 1035.
Man: Anthropogenesis, a Study of the Origin of (Prof. Ant. Pannikoev), review by Dr. J. S. Weiner, 839.
Man and Animals: Fungi Pathogenic to, 476.
Man and Number (Donald Smeltzer), review, 928.
Man-made World: Tomorrow a Already Here, Scenes from a (Robert Jungk), translated from the German by Marguerite Waldman, 1199.
Man-power in Britain: Scientific and Technical, 321.
Management: The Principles and Practice of (edited by E. F. L. Brech), review by T. H. Hawkins, 792.
Study of, review by T. H. Hawkins, 792.
Management of Public Corporations, 477.
Manchester Joint Research Council: Industry and Science, a Study of their Relationship based on a Survey of Firms in the Greater Manchester Area, 1950-1953, 741.
Manchester Literary and Philosophical Society: Election of Officers, 1025.
Manchester Public Libraries: Report for 1952-53, 666.
Mandlberg, J. H.: Physical Chemistry made Plain, review by G. Fowles, 232.
Manganese, a Co-factor of Oxidative Phosphorylation (Olov Lindberg and Lars Ernster), 1038.
Manganese Complexes by Paramagnetic Resonance Absorption: A Study of (Mildred Cohn and Jonathan Townsend), 1090.
Manley, Prof. Gordon: Changes in World Geoclimatology, 1206.
Manly, Brenda M. (Barnett, S. A., and): Breeding of Mice at -3°C, 355.
Manna, Dr. G. K.: Chromosome Number of Human Endometrium, 271.
Manske, R. H. F., and Holmes, H. L. (edited by): The Alkaloids, review by Dr. Harold King, 93.
Mantle Cavity of *Pinna carolinensis* (Prof. C. M. Yonge), 428.
Manton, Prof. L.: Cytology of *Meloidae* in *Motus*, 453.
Awarded the Trail Award and Medal of the Linnean Society of London, 571, 1025.
Grant of 700 dollars from the Rockefeller Foundation of New York towards travel and living expenses in visiting the United States, 1080.
Manton, Dr. S. M.: Recent Advances in Animal Morphogenesis, 519.
Manures and Fertilisers (Dr. A. M. Smith), review, 183.
Manzoni, Sir Herbert: Appointed chairman of the Building Research Board, 476.
Maps of Africa South of the Sahara (Scientific Council for Africa South of the Sahara, Publication No. 4), 428.
Maps of the British Flora: Distribution (Dr. S. M. Walters), 1079.
March, E. W.: Appointed conservator of forests, Nigeria, 896.
Marchant, G.: Reappointment as lecturer in geology at the University of Birmingham, 1025.
Marchant, June, and others: Induction of Ovarian Tumours with 9-10-Dimethyl-1:2-Benzanthracene, 307.
Marcus, Dr. E.: Elected a foreign member of the Linnean Society of London, 1025.
Marcus, Prof. Ernesto, and Macrae, William: Archimetry in a Species of *Composita*, 130.
Marcus, Philip I. (Taleay, Prof. Paul, and): Enzymatic Formation of 3 α -Hydroxysteroids, 1189.
Mardon, P., and others: Some Physical Properties of Metallic Plutonium, 535.
Marfatia, Urmila, and others: Non-participation of Folic Acid in the Biosynthesis of Methyl Compounds from Precursors, 359.
Margarin, Vitamin Standards for, 980.
Vitaminization of, 475.
Marginal Land in Britain (Prof. W. Ellison), review, 539.
Marine Trench: The Greatest Oceanic Sounding and the Topography of the (Dr. T. F. Gaskell, J. C. Swallow and Comdr. G. S. Ritchie), 528.
Marine Lignin: Observations on the Iodo-Amino-Acids of, using Iodine-131 (Richard Scott), 1098.
Marine Biology in Natal (Robert Clarke), 1164.
Marine Biology or Oceanography: Grants in aid of Research in (Challenger Society), 1026.
Marine Bivalves of California: Common (John E. Fitch), 570.
Marine Invertebrate Preparations useful in the Bioassay of Acetylcholine and 5-Hydroxytryptamine (Dr. John H. Welsh), 955.
Maritime Industries: Fifteenth French National Congress of Fisheries and, 981.
Mark, Prof. Herman F.: Honorary fellowship of the Weizmann Institute of Science conferred on, 67.
Markham, Dr. Roy, and others: Evidence for the Existence of Two Types of Ribonucleic Acid, 537.
Marley, Dr. W. G.: Atmospheric Contamination in Industry and the Health of the Worker, 1079.
Marsden, Dr. E.: Appointed by the Royal Society to be Rutherford Memorial Lecturer for 1954, 1026.
Marsh, R. E.: Structure of Proteins, 58.

 Pirlole, C., and others: Presumed Anti-tubercular Activity of 4-Amino-6-Hydroxy-iso-Phthalic Acid, 588
Platycodon grandiflorus, *Megastropus* and the *Austroplatycodinae* (Prof. G. H. R. von Koenigswald), 795
 Pitt, Francis: The Shorehooter, *review*, 8
 Pitt-Rivers, Dr. Rosalind V.: Elected a Fellow of the Royal Society, 568
 Pitt Rivers Museum: Occasional Papers on Technology, 6, Stone-workers' Progress, a Study of Stone Implements in the Pitt Rivers Museum (Sir Francis H. S. Knowles), *review* by M.C.B., 327
 Pittman, David D., and Lindgren, Prof. Carl C.: Long-Term Adaptation to the Fermentation of Galactose in *Saccharomyces cerevisiae*, 408
 Pituitary Gland: Relation of the Paraventricular Nucleus to the (Hans Olfendick), 1001
 Pituitary Glands (Sheep): Isolation and Properties of α -Corticotropin from (Prof. Choh Hao Li, Irving I. Geschwind, Anthony L. Levy, J. Ivan Harris, Jonathan S. Doxon, Ning G. Pan and Jerker O. Porch), 251
 Pituitary Hormone: Synthesis of, 1215
 Placenta of Mice and Rats: Mammoderm berghel in the—Transmission of Specific Immunity from Mother Rats to Litters (Leonard J. Bruce-Chwatt), 353
 Planck (Max) Society: Harnack Medal awarded to Prof. Otto Hahn, 473
 Planetary Nebulae: Photoelectric Spectrophotometry of (Donald A. MacRae and Jürgen Stock), 589
 Planets: The, their Origin and Development (Prof. Harold C. Urey), *review* by Dr. R. Stoenley, 1154
 Planck Studies (Richard Baldwin), 337
 Plant Alkaloids: Handbook of the, *review* by Dr. Harold King, 93
 Plant Form and Function (Prof. F. E. Fritsch and Sir Edward Salisbury), new edition, *review* by Prof. D. H. Valentine, 700
 Plant Genes, their Nature and Definition (G. H. M. Lawrence, I. W. Bailey, Arthur J. Earnes, Reed C. Rollins, Marlon S. Cave and Herbert L. Mason), *review* by Dr. W. B. Turnbull, 908
 Plant-Geography Ancient and Modern, *review* by W. T. Stearn, 1155
 Plant Growth in Water Culture: Liberation of Boron from 'Pyrex' and 'Hyd' Glass in relation to (Dr. I. M. Selman, J. R. Rees and J. Dilnot), 957
 Plant Kingdom: A Review of the, *review* by Prof. F. W. Jane, 279
 Plant Morphology (Prof. Arthur W. Heape), *review* by Prof. F. W. Jane, 279
 Plant Names in Australia: Standardized (Commonwealth Scientific and Industrial Research Organization, Bulletin No. 272), revised version, 805
 Plant Physiology: Annual Review of (edited by Daniel I. Arnon and Leonard Machlis), Vol. 4, *review* by Prof. W. Soles, 842
 The Progress of, *review* by Prof. W. Soles, 842
 Plant Tissue into Individual Cells: A Technique for combining the Seaming of Fused Nuclear Material with the Subsequent Separation of (B. J. Harris and Prof. G. E. Blackman), 642
 Plants: Juvenile Stages of, and the Nutritional Status of the Shoot Apex (A. Allsopp), 1032
 Vascular, common to the Arctic and the British Isles (Dr. Nicholas Polunin), 816
 Plants (Amazonian): Scenoid Sepogonals in (Dr. R. F. A. Altmann), 1098
 Plants (Flowering): The Geography of the (Prof. Ronald Good), second edition, *review* by W. T. Stearn, 1155
 Plants of Downs and Dunes, *review* by Prof. R. C. McLean, 94
 Plants of India: Poocony (Sir Ram Nath Chopra, Rattan Lal Badhwar and Prof. Sudhanshu Ghosh), Vol. 1, *review* by Dr. N. L. Bor, 745
 Plants from New Zealand: Palaeozoic (D. R. McQueen), 88
 Plasma (Platelet-rich Human): Blood Coagulation—Evidence of an Antagonist to Factor VI in (Dr. C. S. Kingsley), 723
 Plasminogen: Role of (Prof. Adrian Srb), 685; (Prof. C. H. Waddington), 686
 Plasmodium berghei in the Placenta of Mice and Rats—Transmission of Specific Immunity from Mother Rats to Litters (Leonard J. Bruce-Chwatt), 353
 Plax (Webster) Collection of African Art (William Fagg), 665
 Plaxidi: Scholarship Grants for Education in (Plaxia Industry Education Fund), 1170
 Plaxia Industry Education Fund: Grant of £1,000 a year for two years for Scholarship at the Birmingham College of Technology, 1170
 Platelet-rich Human Plasma: Blood Coagulation—Evidence of an Antagonist to Factor VI in (Dr. C. S. Kingsley), 723
 Play in Domestic Cattle in Britain—an Analysis of its Nature (A. Brownlee), 1081
 Pleococcy in Tomato: Influence of Position of Truss on (Dr. Gordon Haskell), 311
 Pleistocene of China: Status of *Szechuanopithecus* from the (Prof. G. H. R. von Koenigswald), 643
 Pleistocene Geology of Britain (Prof. F. E. Zeuner), 1178
 Plesch, Dr. P. H. (edited by): Cationic Polymerization and related Complexes, *review* by Dr. N. Græhle, 918
 Plesner, K. W., and Cook, K. A.: Anomalous Temperature Coefficient of Permeability in Barium Titanate, 682
 Plough and Pasture, the Early History of Farming, Part 1, Prehistoric Farming of Europe and the Near East (E. Cecil Curran); Part 2, Farming of Non-European Peoples (Prof. Gudmund Hatt), *review* by Sir John Russell, 916

- Platocum (Metallite): Some Physical Properties of (W. B. H. Lord), 534;
(J. G. Bell, J. A. L. Robertson, P. Mardon, J. A. Lee and E. T. Adams), 535
- Pneumococci: Experimentally produced 'Polyagglutinability' (T-Transformation of Erythrocytes *in vivo*) in Guinea Pigs Infected with (P. Eby-Poulson), 82

 Probability ('Objective'): Philosophical Analysis of, in Science, review by Prof. Jerzy Neyman, 603
 Probability and Information Theory, with Applications to Radar (P. M. Woodward), review by Dr. D. Gabor, 793
 Production of Identical Twins in Rabbits: Attempted Experimental (M. Brochart), 160
 Production of Incomplete Influenza Virus: Artificial (Dr. S. Fazelou de St. Groth and Doris M. Graham), 637
 Productivity in House-Building, Second Report (Department of Scientific and Industrial Research, National Building Series, Special Report No. 21), 69
 Professional Civil Servants, Institution of: Annual Report for 1953, 1073
 Progesterone in Oestrous Behaviour of the Ewe: Relationship of Oestrogen and (Dr. T. J. Robinson), 878
 Progesterone Secretion in Ewes (D. G. Edgar), 639
 Programme Design for Automatic Digital Computing Machines: Summer School in (University Mathematical Laboratory, Cambridge), 981
 Progress, Vol. 43, No. 241 (Unilever, Ltd.), 666
 Promotion of Field Studies, Council for the: Report for 1952-53, 712
 Courses, 760
 Properties of the Calcium Phosphates (Dr. C. A. Beevers and B. Rabinick), 542
 Properties of α -Corticosterone from Sheep Pituitary Glands: Isolation and (Prof. Choh Hao Li, Irving I. Geschwind, Anthony L. Levy, J. Levan Harris, Jonathan S. Dixon, Nmg G. Pon and Jerker O. Porath), 251
 Properties of Matter (Dr. F. C. Champion and Dr. N. Davy), second edition, review, 373
 Properties of 2-Methoxy-2 : 4 : 4 : 7 β -Pentamethylflavone: Some Anomalous (D. J. C. Wood), 1149
 Prostatic Phosphatase on Ion-exchange Resin: Adsorption of (Dr. Hans G. Boman), 447
 Prostatic Group of Cytochrome α_1 (J. Barrett and Dr. R. Lemberg), 213
 Protection of Birds in Britain, 225
 Protection of the Body: Mucins and the (Sir Howard Florey), 385
 Protein in Developing Root Cells (C. Morgan and W. S. Keith), 1074
 Protein Hydrolysis: Threonine and the Odour of (Dr. D. M. P. Phillips), 1092
 Protein Metabolism in Leaves (Prof. A. C. Chibb and G. H. Wiltshire), 1082
 Protein Solutions: Refractive Index of Concentrated (Dr. R. Barer and S. Tlacznyk), 821
 Protein Structure: Possible Relation between Deoxyribonucleic Acid and (Prof. G. Gamow), 318
 Protein Synthesis and Amino-Acid Incorporation in Disrupted Staphylococcal Cells: Effect of Nucleic Acids on (Dr. E. F. Gale and Joan P. Folkes), 1223
 Protein Synthesis and Genetics (Dr. Allen S. Fox), 350
 Protéines: Les Rapports et discussions (Institut International de Chimie Solvay, Neuronne Conseil de Chimie tenu à l'Université de Bruxelles du 6 au 14 avril 1953), review, 141
 Proteins: Anhydrous Hydrogen Fluoride as a Solvent for (Joseph J. Katz), 265
 The Chemistry, Biological Activity and Methods (edited by Hene Neurath and Kenneth Bailey), Vol. 1, Part A, and Vol. 1, Part B, review by Dr. D. P. Riley, 1059
 Some Conjugated, a Symposium (Six lectures presented at the Ninth Annual Conference on Protein Metabolism held at the Bureau of Biological Research, Rutgers University, State University of New Jersey, January 30-31, 1953), edited by William E. Cole, review, 141
 The Physical Chemistry of (Discussions of the Faraday Society, No. 13), review, 8
 Selective Absorption of Optical Antipodes by (W. Bradley and Prof. R. A. Brindley), 312
 Structure of (Conference at the California Institute of Technology), 57
 Proteins and their Nature, review by Dr. D. P. Riley, 1059
 Processes, Simple and Complex, review, 141
 Protein (Milk): Enzymic Isolation of (Dr. Mary T. McQuillan, Dr. R. K. Morton, P. G. Stanley and Prof. V. M. Tricoli), 305
 Proteins (Soluble Liver-Cell): Electrophoretic Separation on Filter Paper of the of the Rat using Borate Buffer (G. Adjuntas), 539
 Proteins and Enzymes (Kj) Ulrik Linderström-Lang, review by Dr. Kenneth Bailey, 607
 Proton Magnetic Resonance Study of the Hydration of Deoxyribonucleic Acid (Dr. Bertal Jacobson, Wacq A. Anderson and James T. Arnold), 772
 Proton Polarization at ≈ 130 MeV. (J. M. Dickson and D. C. Selter), 946
 Protons (Fast): Probable Side-effect of Nuclear Reactions in the Biological Action of (Dr. Lars Ehrenberg and Dr. Göran Andersson), 1086
 Protons of Energy up to 21 MeV.: Range-Energy Relation in Nuclear Track Emulsions for (Dr. W. M. Gibson, D. J. Prowse and Prof. J. Rabinick), 1180
 Protozoenkunde: Lehrbuch der (begründet von Franz Doflein), sechste Auflage, Teil 2, Spezielle Naturgeschichte der Protozoen, Hefte 2, Sporozoen und Ciliophora, review by Dr. G. Lapage, 966
 Proudman, Prof. J.: Dynamical Oceanography, review by Sir Harold Jeffreys, 232
 Recruitment from the chair of oceanography in the University of Liverpool, 1022; work of, 1022
 Prowse, D. J. and others: Range-Energy Relation in Nuclear Track Emulsions for Protons of Energy up to 21 MeV., 1180
 Pruszy, Dr. F. T. G.: Title of professor of chemical pathology in the University of London conferred on, 981
 Pruvost, Prof. P.: Elected a member of the Mineralogical Section of the Paris Academy of Sciences, 1171
 Pryce, Prof. M. H. L.: Appointed Henry Overton Wills professor of physics in the University of Bristol, 710; work of, 710
 Pryde, J.: Appointed veterinary officer, Kenya, 112
 Pryor, E. J.: Recent Developments in Mineral Dressing, review, 97
 Mineral Dressing at the Royal School of Mines, London, 565
 Pryor, Thomas: Honorary membership of the Institution of Mining and Metallurgy conferred on, 895
 Psychological Reflections, an Anthology of the Writings of C. G. Jung (selected and edited by Jolande Jacobi), review by Dr. H. Westermann, 842
 Psychology: Logic and (Jean Piaget), review, 927
 Psychology of Personality, review by Prof. L. S. Hamshaw, 911
 Psychology of Spectres, review by Dr. E. J. Dingwall, 912
 Pyridyl Pyrimidine: Action of Systemic Insecticides on the (John Nicol), 56
 Pyridines: The Monosubstituted (Prof. Adrien Albert), 1046
 Recent Advances in the Chemistry and Biology of the (Ciba Foundation Symposium on), 1175
 Public Analysts and other Analytical Chemists: The Contribution of, to Public Welfare (Dr. E. B. Hughes), 526
 Public Analysts and other Analytical Chemists, Society of: Name changed to the Society for Analytical Chemistry, 109
 Public Corporations: Management of, 477
 Public Welfare: The Contribution of Public Analysts and other Analytical Chemists to (Dr. E. B. Hughes), 526
 Public Welfare Medal of the National Academy of Sciences, Washington, presented to Dr. Alan Gregg, 1172
 Publish Scientific Results: Failure to (Prof. P. A. Buxton), 410; (Dr. W. J. Hall), 784
 Puccinia graminis found in Kenya: Seedling Resistance and Mature-Plant Susceptibility of Wheat to (A. D. S. Duff), 779
 Puccinia polymorpha: Resistance to the Mass Rust (Dr. H. H. Storey and A. K. Ryland), 778
 Puccinia polymorpha Underwood in the Indian Ocean Area: Occurrence of (G. Orfan), 505
 Puerto Rico and Barbados, West Indies: Submarine Landlips off the Coasts of (Raoul C. Mitchell), 119
 Pulse Amplifiers: Nuclear, review by E. H. Cooke-Yarborough, 371
 Pumphrey, Prof. R. J.: Acoustics of Orthoptera, 1219
 Puncture Acid: Spectroscopic Examination of (N. H. E. Ahlers, A. C. Dennison and L. A. O'Neill), 1045
 Pupae of Microbracon bronchialis Wesm.: Effect of Refrigeration of the, on the Pigmentation of the Adult (E. S. Narayanan, G. W. Angalet, B. R. Subba Rao and G. L. D'Souza), 503
 Purcell, Dr. R. H.: Appointed scientific adviser to the Home Office, 473; work of, 473
 Purdue University, and others: Conference on Soil Microbiology, 896
 Purified Casein for Nutritional Research (Alice M. Copps), 1165
 Purcell, M. F.: Appointed and survey officer, Gold Coast, 112
 Purple: Human Visual, and Absolute Threshold (Dr. M. H. Pirrane), 215
 Purple Level (Visual), and the Course of Dark Adaptation (Dr. W. A. H. Rushton and R. D. Cohen), 301
 Purselove, J. W.: Appointed director of botanical gardens, Singapore, 1171
 Putnam (Helen) Fellowship for advanced research, 112
 Putnam, J. L. (Whitehouse, W. J., and): Radioactive Isotopes, review by Dr. S. J. Thomson, 919
 Putnam, Palmer Consett: Energy in the Future, review by Prof. Frank Debenham, 1013
 Pykno-X-Ray Method: Determination of Atomic Masses by the (Prof. T. Bethe), 345
 Pyramidal Configurations (Tetragonal): Metal-Oxygen Bonds, and Co-ordination Complexes with (Dr. George Philip and D. H. Irvine), 1148
 'Pyrex' and 'Hyal' Glass: Liberation of Boron from, in relation to Plant Growth in Water Culture (Dr. I. W. Selman, J. R. Rees and J. Dilnot), 957
 Pyridinecarboxylic Acids: Paper Chromatographic Separation of the Isomeric (Takashi Hasegawa), 645
 Pyruvic, Oxalacetic and α -Ketoglutaric Acids: Chromatographic Separation and Analysis of Mixtures of (P. A. Isherwood and D. H. Crickshank), 121
 QUALITATIVE Analysis: Notes on (H. J. H. Fenton), new edition by Dr. B. C. Saunders, review by G. Fowles, 929
 Small-scale Inorganic (Dr. J. T. Stock and P. Heath), review by G. Fowles, 928
 Quality of Soybean Oil Meal: Relation between the, and the Requirements of Vitamin B₁₂ for Chickens (Allan Frolich), 132
 Quality in Tea: Morphological Basis of (W. Wight and P. K. Baner), 630
 Quantitative Biology (Cold Spring Harbor Research Symposium on), (The Mammalian Fetus—Physiological Aspects of Development), 430
 Quantitative Evaluation of Paper Chromatograms by Infra-red Absorption (Dr. J. D. S. Goulden), 646
 Quantitative Inorganic Analysis: Textbook of (Prof. I. M. Kolthoff and Prof. E. B. Sandell), third edition, review by C. O. Harvey, 463
 Quantitative Method for Enzyme Cytochemistry applied to Alkaline Phosphatase (H. G. Davies, R. Barter and Prof. J. F. Danielli), 1234
 Quantitative Method for Growing Animal Cells in vitro (Dr. L. M. Rialdini), 1134
 Quantum Mechanics: Measurement of Length and Angle in (Prof. E. Schrödinger), 442
 Quarrell, Prof. A. G.: The Oxidation of Metals, review, 922
 Quarterly Journal of Microscopical Science: Centenary Number of the, 669
 Quartz (Smoky): Paramagnetic Resonance in Neutron-Irradiated Diamond and (Dr. J. H. E. Griffiths, J. Owen and I. M. Ward), 439
 Quartz Clock Error and Frequency Drift: Annual Fluctuations in (H. J. M. Abraham), 73
 Quastel, Prof. J. H.: Soil Metabolism (Lecroenhoek Lecture of the Royal Society), 385
 Soil Metabolism, 1213
 Quaternary Ecological Studies in Ireland, 18
 Queen, H. M. the: Birthday Honours List, 1168
 Queen Elizabeth College, London: Appointment of Prof. John Yudkin to the University of London chair of nutrition, 292
 Queen Mary College, London: Appointment of Prof. A. D. Young to the University of London chair of aeronautical engineering, 64
 Title of professor of civil engineering in the University of London conferred on J. W. H. King, 292
 Queen Mary College, London (Chemistry Department): Symposium on Molecular Rearrangements in Organic Chemistry, 898
 Queen's University, Belfast: Gift of £12,000 from the Nuffield Foundation for research in Quaternary Ecological Studies, 18
 Appointment of Dr. Alwyn Williams to the chair of geology, 112, 289

- Appointment of Dr. John Heslop-Harrison to the chair of botany, 112, 150
- Retirement of Prof. J. Small from the chair of botany, 150
- Retirement of Prof. J. K. Charlesworth from the chair of geology, 269
- Appointment of Dr. R. A. Raphael as professor of organic chemistry, 336
- Appointment of Dr. H. Schneider as lecturer in pure mathematics, 714
- Appointment of Dr. J. Lowy as lecturer in experimental zoology, 714
- Appointment of Dr. H. G. Heal as lecturer in chemistry, 714
- New Geology Building (Prof. J. K. Charlesworth), 891
- Appointment of N. Stephens as lecturer in zoography, 1073
- Appointment of E. R. Redfern as lecturer in biochemistry, 1075
- Appointment of A. G. Smith to a senior research post in the Department of Botany, 1075
- Appointment of Dr. B.-L. Moltenwisch as a supernumerary lecturer in applied mathematics, 1075
- New Institute of Clinical Science at the, 1208
- Queen's University, Kingston, Canada: Appointment of Dr. J. K. N. Jones as Chown research professor in chemistry, 107
- Quickfit and Quartz, Ltd.: Gift of £50 to Norwood Technical College, London, for an annual prize for the best student of advanced chemistry, 1075
- Quill, N. R.: Appointed development officer, Agricultural Department, Somaliland Protectorate, 112
- Quirk, J. P. (Norman, K., and): Crystalline Swelling of Montmorillonite—Use of Electrolytes to control Swelling, 255
- Quynn, Richard G., and Steele, Richard.: Infra-Red Dichroism of Nylon and Polyethylene Terephthalate, 1240
- RABBIT:** Milk Ejection resulting from Mechanical Stimulation of Mammary Myoepithelium in the (B. A. Cross), 450
- Observation of *in vitro* Fertilization in the (R. Morford), 1140
- Rabbit in Tasmania. Genetic Polymorphism in the (Prof. H. N. Barber), 1227
- Rabbit Uterus (Pregnant): Bicarbonate Content of the Blastocyst Fluid and Carbonic Anhydrase in the (Dr. C. Lutwak-Mann and Dr. H. Lasser), 268
- Rabbit Vagina: Absorption of Phosphorus-32 from the, under various Hormonal Conditions (Dr. Lars Ph. Bengtsson), 954
- Rabbits: Attempted Experimental Production of Identical Twins in (M. Brochart), 160
- Rabbits in Great Britain: Myxomatosis in (Dr. G. Lepage), 856
- Rabinowitch, Dr. E.: The Narrowing Way, 242
- Radar: Probability and Information Theory, with Applications to (P. M. Woodward), review by Dr. D. Gabor, 793
- Radar Echoes: Polarization of, from Meteorological Precipitation (I. M. Hunter), 165
- Radar Weather Conference, and others. Symposium on Radio-Meteorology, 761
- Raid, Dr. Ingemar C.: Awarded a National Research Council of Canada Fellowship for Medical Research, 1216
- Radhakrishna Rao, Prof. C.: Elected a Fellow of the National Institute of Sciences of India, 474
- Radiation: Influence of Dissolved Gases on Hydrogen Peroxide Formation and Bacteriophage Inactivation by (Michael Ebert and Tikvah Alper), 937
- Radiation (High-energy): Effect of Molecular Weight on the Cross-Linking of Siloxanes by (Dr. A. Charlesby), 679
- Radiation (Ionizing): Action of, on Aqueous Solutions of Carbohydrates (Dr. G. O. Phillips), 1044
- Radiation (Solar): Forecasting Weather from (Dr. C. G. Abbot), 880
- Radiation Chemistry (Discussions of the Faraday Society, No. 12), review by Prof. J. R. Partington, 930
- Radiation Hazards of Atomic Energy (Dr. J. F. Lourt), 621
- Radiation-suppressing Coatings for Metals at Elevated Temperatures (Dr. A. H. Sully, E. A. Brandes and R. B. Waterhouse), 1074
- Radiation-Widths of Nuclear Energy Levels (Prof. D. J. Hughes and J. A. Harvey), 942
- Radiations (Ionizing): Chemical Primary Processes in the Action of, in Water—Evidence from Experiments with Heavy Water (Patrick Kelly, Dr. Tyson Rigg and Dr. Joseph Weiss), 1130
- Energy Transfer in Macromolecules Exposed to (Dr. P. Alexander and Dr. A. Charlesby), 578
- Preservation of Food with (Food and Microbiology Groups of the Society of Chemical Industry Symposium on), 752
- Radiations in Industry: Precautions in the Use of Ionizing (Ministry of Labour and National Service, Factory Department, Factory Form 324), 251
- Radicals (Free Hydroxyl): Detection of, during the Oxidation of Cellulose in Air (R. Holden), 539
- Radio Asymmetry: Solar, at 4-Metre Wave-length (J. S. Hey and V. A. Hughes), 771
- Radio Echoes: Lunar, and the Faraday Effect in the Ionosphere (W. A. S. Murray and J. K. Hargreaves), 944
- Radio Emission from the Persius Cluster (J. E. Baldwin and B. Elmore), 818
- Radio Engineers, British Institution of: Clerk Maxwell Memorial Lecture (Sir John Cockcroft), 854
- Annual Convention (The Application of Electronics to Industry), 854, 1217
- Radio Engineers, Institute of, and others: Proceedings of the Western Computer Conference held by the Joint IRE-AIEE-ACM Computer Conference Committee, Los Angeles, 200
- Symposium on Radio-Meteorology, 761
- Radio Evidence of the Ejection of Very Fast Particles from the Sun (J. P. Wild, J. A. Roberts and J. D. Murray), 532
- Radio Frequency Noise in a d.c. Hydrogen Arc: Spectrum Intensities and (Dr. S. E. Williams and V. Maslen), 361
- Radio Industry Council: Premiums for Technical Writing, 384
- Radio-Meteorology (American Meteorological Society, the Institute of Radio Engineers, the Radar Weather Conference, and the American National Groups of Commission II of the International Scientific Radio Union and of the Joint Commission on Radio-Meteorology of the International Council of Scientific Unions Symposium on), 761
- Radio Noise: Generation of, by Cosmic Sources (Dr. J. H. Piddington), 482; (F. Hoyle), 483
- Radio Research Board: Report for 1952, 158
- Radio Research Station: New Building for the, 894
- Radio Source in Gemini: Position and Identification of a Bright Extended (J. E. Baldwin and D. W. Dewhurst), 164
- Radio Sources: Galactic, of Large Angular Diameter (R. Hanbury Brown, H. P. Palmer and A. R. Thompson), 945
- Intensities of Discrete, in Cygnus and Cassiopeia at 22.6 Mc/s. (J. S. Hey and V. A. Hughes), 819
- Radio Stars: A Method for the Measurement of the Distance of (D. R. W. Williams and R. D. Davies), 1182
- Radioactive Carbon: Dating by, review by E. M. Jope, 1111
- Radioactive Carbon and Phosphorus: Uptake of, by Parasitized Leaves (Dr. M. Shaw, Dr. Stewart A. Brown and Dr. D. Rudd Jones), 768
- Radioactive Corticosterone, 109
- Radioactive Isotopes (W. J. Whitehouse and J. L. Putman), review by Dr. S. J. Thomson, 919
- Radioactive Substances: Radioactivity and (Sir James Chadwick), fourth edition, review by S. Weintraub, 933
- Radioactive Zinc from Cyclotron-Irradiated Copper: Estimation of Zinc in Biological Specimens—Separation of (R. Tupper and R. W. E. Watts), 349
- Radioactivity and Radioactive Substances (Sir James Chadwick), fourth edition, review by S. Weintraub, 933
- Radiocautographic Studies of the Digestive Tracts of Rats Injected with Inorganic Sulphate labelled with Sulphur-35 (Prof. D. V. Davies and Prof. L. Young), 448
- Radiocarbon and some Applications in Biochemistry (Dr. E. Broda and Dr. L. Svarak), 676
- Radiocarbon Dating (Willard F. Libby), review by E. M. Jope, 1111
- Radiocarbon Facilities at Harwell and Amsterdam. New, 1067
- Radiocollimators, Société des: International Meeting on Methods of Sound Recording and their Applications in Different Fields, 63
- Radio-Frequency Brightness across the Solar Disk. Distribution of, and the Derivation of a Model Corona (P. A. O'Brien and C. J. Bell), 219, erratum, 245
- Radiolanthanum Conference. Second (Atomic Energy Research Establishment), 245
- Radiolanthanum: Pile Production of, by Threshold Reactions (Prof. D. J. Hughes), 396
- Radiolanthanum in Industry (edited by John R. Bradford), review by W. S. Eastwood, 97
- Radley, J. A.: Starch and its Derivatives, Vol. 2, third edition, review by Prof. J. R. Partington, 930
- Radio, Dr. R.: Appointed to the chair of mathematics at the University of Reading, 1169; work of, 1169
- Radovi Medicinskiog Fakulteta u Zagrebu, Vol. 1, 525
- Radt, F. (edited by) Elsevier's Encyclopaedia of Organic Chemistry, Series 3, Carbocyclic Condensed Compounds, Vol. 128, Naphthalene, A; No. 5, Compounds containing One Naphthalene Nucleus, Naphthoquinones and other Polyketohydronaphthalenes; No. 6, Compounds containing One Naphthalene Nucleus, Carboxylic Acids (CO₂H in Side Chain), review by Prof. F. W. Cook, 370; Series 3, Carbocyclic Condensed Compounds, Vol. 14, Supplement, Triterpenes (co-edited by Dora Stern), review, 418
- Railkes, Dr. Humphrey R.: Retirement as vice-chancellor and principal of the University of the Witwatersrand, 17; work of, 17
- Rain: Artificial Stimulation of, 1212
- Rain-making: Research Into, 474, 1212
- Rainbow, C. (Hopkins, Prof. R. H., and) La Chimica delle Fermentazioni, review, 515
- Raistrick, Dr. B.: Elected a Fellow of the Royal Society of Edinburgh, 474
- Raistrick, Dr. B. (Beavers, Dr. C. A., and): Properties of the Calcium Phosphates, 542
- Ramstedt, R.: Awarded a Dorton Prize for 1953 of the Royal Meteorological Society, 807
- Ramberg, Prof. Hans: The Origin of Metamorphic and Metasomatic Rocks, review by Prof. H. H. Read, 913
- Ramm, C. A.: High-Energy Accelerators, 1127
- Ramo, Dr. Simon: An Evaluation of Analog and Digital Computers, 200
- Ramsay Memorial Fellowships Trust: Fellowships for Chemical Research, 430
- Ramsbottom, Dr. J.: Elected president of the Society for the Bibliography of Natural History, 525
- Ranby, Dr. P. W.: Luminescence of Inorganic Phosphors, 1077
- Rand, M. H.: Fast Chemical Reactions, 1163
- Randall, Prof. H. M.: Presented with the Frederic Ives Medal of the Optical Society of America, 1170
- Randle, T. C.: Cosmic Radiation, 1128
- Raney Nickel Catalyst: Thermal Treatment of (Ijro Yasumura), 80
- Range-Energy Relation in Nuclear Track Emulsions for Protons of Energy up to 21 MeV (Dr. W. M. Gibson, D. J. Prowse and Prof. J. Rotblat), 1180
- Rankin, P. A.: Airborne Magnetic Surveys, 281
- Rankin, Prof. R. A.: Rockets, Missiles and Space Travel, review, 183
- Appointed to the chair of mathematics in the University of Glasgow, 615
- Ranunculus: Effect of Temperature on Leaf-shape In (F. J. F. Fisher), 406
- Rao, K. Suryanarayana: Rotational Analysis of the Columbian Oxide Bands, 1240
- Raphael, Dr. R. A.: Appointed professor of organic chemistry at Queen's University, Belfast, 336; work of, 336
- Rapid Compression: Ignition of Methane-Air Mixtures by (N. P. W. Moore and J. R. Simonson), 543
- Raspberries (Virus-infected): Heat Therapy of (J. Chambers), 595
- Rat: Electrophoretic Separation on Filter Paper of the Soluble Liver-Cell Proteins of the, using Borate Buffer (G. Adjutant), 539
- Rat Eggs (Unfertilized): Nuclear Formation and Cleavage induced in (C. R. Austin and A. W. H. Braden), 999
- Rat Kidneys: Histochemical Effect in (William J. P. Neish), 308
- Rat Lung-worm: Life-history of the, and its Migration through the Brain of its Host (M. Josephine Mackerras and Dorothy F. Sanders), 956
- Rat Thyms Homogenates: Physical State of Deoxyribonucleic Acid in (Dr. K. V. Shooter), 824
- Rate of Growth of Fish: Influence of Mammalian Growth Hormone on (D. R. Swift), 1096
- Rate of Sorption of Gases on to Getter Materials. Influence of Electronic Impact on the (Dr. S. Wagener), 684
- Rate Equation in Chemical Kinetics: Formulation of the (P. V. Danckwerts), 222

- Rates of Adsorption: Effect of Surface Diffusion on (D. Patterson), 1184
 Ratgeber, Dr. H. D.: Appointed a member of the experimental team in the School of Physics of the University of Sydney, 241
 Ratio between the Water-soluble Aromatic and Nitrogenous Constituents of Apple and Pear in the Host-Parasite Relationships of *Venturia* Species: Significance of the (D. S. Kirkham), 690
 Rationalism in Antiquity (Prof. L. Rosenfeld), 341
 Rados in Yeast: Polymeric Zygotes as a Source of Polyploidy and Irregular (Dr. Majeed Ahmad and Azeaz Khan), 133
 Rats: Fluorine in Ties and Cakes in (L. Gershon-Cohen and Prof. J. F. McClelland), 304
Plasmodium berghei in the Placenta of Mice and—Transmission of Specific Immunity from Mother Rats to Litters (Leonard J. Bruce-Chwatt), 353
 Rats (Malayan Forest): Moonlight and the Pregnancy of (J. L. Harrison and N. van der Bijl), 1002
 Rats Injected with Inorganic Sulphate labelled with Sulphur-35: Radioautographic Studies of the Digestive Tracts of (Prof. D. V. Davies and Prof. L. Young), 448
 Raven, Rev. Charles E.: Natural Religion and Christian Theology, review by Prof. A. D. Ritchie, 279
 Raven, Prof. Chr. P.: Recent Advances in Animal Morphogenesis, 518
 Raw Materials: The Control of (J. Hurstfield), review by E. D. McCallum, 53
 Rawlins, F. L. G.: Aesthetics and the Gestalt, review by Dr. Martin Johnson, 230
 Rawlins, F. L. G. (edited by): The Faraday Society—The First Fifty Years, 1903-1953, review by Prof. H. N. Rydon, 936
 Rawson, H.: Reduction in the Loss Factor of certain Ceramics by Heat Treatment, 447
 Rawson, H., and others: Vanadate Glasses, 1030
 Rawson, Sir Stanley: Engineering Dimensional Metrology, 294
 Reaction: The Girard (D. A. Forre and E. A. Dunstone), 401
 Reaction (Hill): Kinetic Evidence for New Participants in the (Dr. H. S. A. Gilmore, Dr. Rufus Lumry and Dr. John D. Spikes), 31
 Reaction (Nihydrin): Detection of Fingerprints by the (Svante Odén and Bengt von Holsten), 449
 Reactions: Inorganic Kinetics and (Chemical Society Symposium on), 670
 Investigations of Rates and Mechanisms of (Technique of Organic Chemistry, Vol. 8), (edited by S. L. Friess and A. Weissberger), review by Dr. J. C. D. Brand, 918
 Unimolecular Gas (Discussion in the Department of Chemistry, University College, London), 809
 Reactions (First Chemical): The Study of (Faraday Society Discussion on), 571, 1162
 Reactions (Nuclear): Probable Side-effect of, in the Biological Action of Fast Protons (Dr. Lars Ehrenberg and Dr. Goran Andersson), 1086
 Reactions (Organic): The Mechanisms of, review by Dr. W. A. Waters, 278
 Reactions (Threshold): Pile Production of Radiosotopes by (Prof. D. J. Hughes), 396
 Reactions of the Human Body to Injury (Dr. V. Udell), 1173
 Reactions of Mechanoerythrin and Catalase with Peroxides and Hydrogen Donors (Prof. D. Keilin and Dr. E. F. Hartree), 720
 Reactor Theory (Nuclear): The Elements of (Dr. Samuel Glasstone and Milton C. Edlund), review by P. W. Mumery, 921
 Read, Prof. H. H.: Elected a correspondent for the Mineralogical Section of the Paris Academy of Sciences, 244
 Origin of Metamorphic Rocks, review, 913
 Read, Prof. John: Organic Syntheses, review, 655
 Read, L. Hector: Varieties in relation to Crop Production, 199
 Reading, Capt. O. S.: Engineering Dimensional Metrology, 294
 Reagents for Amino-Acids: Aromatic Aldehydes as Specific Chromatographic Colour (G. Curzon and J. Giltrow), 314
 Reasco, R. E.: Engineering Dimensional Metrology, 295
 Receptors and Sensory Perception (Prof. Ragnar Granit), 526
 Recolonization of Sterilized Soil by Micro-organisms. Soil Recolonization Tube for studying (E. Evans), 1196
 Recombination in the α -Layers (Dr. A. L. Stewart), 165
 Red-Cell Ghosts (Human): Rehydration of (Dr. Eric Ponder), 1139
 Red Cells: Physical Instability and Thermal Shock in (Dr. J. E. Lovelock), 659
 Red Cells (Human): Phosphate Partition and Turnover in (Dr. T. A. J. Prankerd and Dr. K. L. Altman), 670
 Red Cells in Normal Individuals: Short-lived (Robert L. Evans), 129
 Reddi, Dr. K. K., and Norstrom, Alvin: Influence of Vitamin C on the Utilization of Sulphate labelled with Sulphur-35 in the Synthesis of Chondroitin Sulphate of the Costal Cartilage of the Guinea Pig, 1232
 Redfern, E. R.: Appointed lecturer in biochemistry at Queen's University, Belfast, 1075
 Redhead, J. F.: Appointed assistant conservator of forests, Nigeria, 570
 Redinha, José: Subsidios para a História, Arqueologia e Etnografia dos Povos da Lunda, review by M. C. Burkitt, 229
 'Reducing' Sugars and other Carbonyl Compounds: A Rapid Gasometric Method of Analysis for (Dr. Philip S. Skell and Joseph G. Crirt), 401
 Reduction in the Loss Factor of certain Ceramics by Heat Treatment (H. Rawson), 447
 Reduction of Tetrazolium Salt (B. Jámor), 774
 Reduction by X- and γ -Rays of some Substances of Biological Interest (Dr. Gabriel Stein and Dr. A. J. Swallow), 937
 Redwood Medal of the Institute of Petroleum awarded to Dr. F. P. Bowden, 20
 Reed, R. F. A. L.: Appointed principal of schools, Agricultural Department, Western Region, Nigeria, 194
 Rees, A. R.: Awarded a Colonial research studentship with the view of appointment as a scientific officer (plant physiology), 760
 Rees, H., and Jamieson, A.: A Supernumerary Chromosome in *Loxostoma*, 43
 Rees, J. R., and others: Liberation of Boron from 'Pyrex' and 'Hysil' Glass in relation to Plant Growth in Water Culture, 957
 Reflecting Films: Multilayer Dielectric, at Wave-lengths between 4000 and 4600 Å (J. Ring and W. L. Wilcock), 994
 Refractive Index of Concentrated Protein Solutions (Dr. R. Barer and S. Tinoczyk), 821
 Refrigeration of the Pupae of *Microbrachy brevicornis* Wezm.: Effect of, on the Pigeonization of the Adult (E. S. Narayanan, G. W. Angeles, B. R. Subba Rao and G. L. D'Souza), 503
 Refugee Scholars: The Rescue and Achievement of (Norman Bentwich), review by Dr. H. E. Wimperis, 1201
 Rega, D. V., and Sreenivasan, Dr. A.: Influence of Folic Acid and Vitamin B₁₂ on the Impairment of Nucleic Acid Synthesis in *Lactobacillus casei* by Aureomycin, 728
 Regional Council for Further Education for the South West: Courses on the Rationalized Metric-Kilogram-Second System, 64
 Regional Survey of Croydon and District, 1075
 Registrar General: Statistical Review of England and Wales for the Year 1949, Supplement on General Morbidity, Cancer and Mental Health, 531
 Regularities in the Composition of Pentose Nucleic Acids (Dr. David Elion and Prof. Erwin Chargaff), 1037
 Regularities in the F-Region of the Ionosphere (B. Chatterjee), 263
 Rehydration of Human Red-Cell Ghosts (Dr. Eric Ponder), 1139
 Reid, D. M.: Awarded a Leverhulme Research Grant, 1025
 Reid, Mrs. E. M.: Obituary by W. N. Edwards, 190
 Reid, R. T. W., and others: Carcinogenic Azo-compounds, 313
 Reilly, H. Christina, and others: Azaserine, a New Tumour-Inhibitory Substance—Studies with Crocker-Morse Sarcoma 180, 71
 Reinforcing Rubber Pillars: Free-Radical Activity of (Dr. V. A. Garten), 997
 Reinouts van Hags, Dr. P.: Alkaloids in Germinating Seeds of *Atropa belladonna*, 692
 Reith, Lord: Nationalized Industries, 478
 Reith, W. S. (Morgan, C., and): Protein in Developing Root Cells, 1074
 Relation between Deoxyribonucleic Acid and Protein Structure: Possible (Prof. G. Gamow), 318
 Relation of the Paraventricular Nucleus to the Pituitary Gland (Hans Olfverson), 1001
 Relative Viscosity and Volume Concentration of Suspensions of Spheres: The Einstein Relation between (A. J. Hughes), 1069; (Donald R. Oliver and Prof. Stacy G. Ward), 1090
 Relaxing Factor in Muscle: Myokinase as a (J. R. Randall), 548
 Relf, Ernest F.: High-Speed Fluid Flow, review, 604
 Religion: Some Aspects of the Conflict between Science and (Prof. H. H. Price), 152
 Natural, and Christian Theology (Rev. Charles E. Raven), review by Prof. A. D. Ritchie, 279
 Science and, review by Prof. A. D. Ritchie, 279
 Religion and the Modern Mind (Prof. W. T. Stace), review by the Very Rev. Dr. W. R. Matthews, 512
 Religion in the Scientific World: The Place of, review by the Very Rev. Dr. W. R. Matthews, 512
 Removing the Causes of War (Dr. Kathleen Lockdale), review by R. B. B. Randle, 8
 Rennie, B. J.: Timber Development, review, 968
 Renner, Prof. Otto: Elected a foreign associate of the National Academy of Sciences, Washington, 1173
 Reproduction in *Maraphys* (G. B. Sherman), 302
 Reproduction in Notostraca (Crustacea) (Alan R. Longhurst), 781
 Rescue and Achievement of Refugee Scholars (Norman Bentwich), review by Dr. H. R. Wimperis, 1201
 Research: Arid Zone (Session in Montpellier of the Unesco Advisory Committee on), 622
 Atomic Energy at Harwell (Sir John Cockcroft), 386
 British Colonial—Report for 1952-53, 374
 Cacao, during 1952-53 (Dr. E. E. Cheesman), 1129
 Deep-sea (Dr. J. B. Tait), 527
 Defence, and the National Economy, 884
 Forestry, in Great Britain (Prof. E. P. Stabbing), 116
 High Altitude Rocket (Homer E. Newell, Jr.), review by Prof. D. R. Bates, 697
 Hydraulic, in the United States (edited by Helen K. Middleton and Sonya W. Matchett), 1215
 Instructional Film, in Pennsylvania (C. Denis Pegge), 937
 Oceanographic, at Woods Hole (United States Navy New Laboratory for), 666
 The Neutron (Prof. D. J. Hughes), review by P. A. Egelfarf, 462
 Road, in Great Britain, 961
 Scientific, in the East (Dr. M. Radduddin Siddiqi), 337
 Scientific, and Exposition, 1199
 Scientific, and Industry in Britain, 787
 Research (Advanced): Helen Pittman Fellowship for, 112
 Research (Agricultural): Careers in (Agricultural Research Council), 429
 Training Grants, Studentships and Fellowships in (Agricultural Research Council), 429
 Research (Arid Zone): Directory of Institutions engaged in, 854
 Research (Atomic): Secrecy and Security in, 835
 Research (Biological, Agricultural and Medical): Statistical Tables for (Sir Ronald A. Fisher and Dr. Frank Yates), fourth edition, review by Prof. J. H. Gaddum, 183
 Research (Cacao): A Report on, 1945-51 (Imperial College of Tropical Agriculture), 115
 Research (Cancer): Katharine Berrian Judd Awards for, 804
 Research (Chemical): Fellowships for (Ramsey Memorial Fellowships Trust), 430
 Research (Clinical): Fellowships for (Medical Research Council), 112
 Research (Deep-Sea): International Collaboration in (Dr. J. D. H. Whetton), 527
 Research (Development): Statistical Design and Analysis of Experiments for (Donald Stetler Villers), review by M. R. Sampford, 327
 Research (Geological): Grants for (Clough Memorial Research Fund of the Edinburgh Geological Society), 339
 Research (Medical): Bert Memorial Fellowship Awards, 981
 Fellowships for (National Research Council of Canada Awards), 1216
 Research (Nuclear): European Organization for, 1169
 Research (Nutritional): Purified Casein for (Alice M. Copping), 1165
 Research (Phys. ca): Mass Spectroscopy in (Proceedings of the National Bureau of Standards Semicentennial Symposium on Mass Spectroscopy in Physics Research), review by G. H. Palmer, 373
 Research (Virus): Advances in (edited by Kenneth M. Smith and Max A. Lauffer), Vol. 1, review by F. C. Bawden, 324
 Research in Commonwealth Countries: Bursaries for (Royal Society and the Nuffield Foundation), 151
 Research in Scotland: Co-ordination of (J. Stuart), 383
 Research in Ferrous Metallurgy: Fellowship for (Endowed by the United Steel Companies, Ltd., at the University of Sheffield), 476
 Research in Marine Biology or Oceanography (Challenger Society grants in aid of), 1026
 Research in Parasitology: Latin American, 664

- Research into Rain-making, 474, 1212
 Research in Schistosomiasis and its Vectors, 556
 Research in Vacuum Techniques: Development and, 961
 Research and the Future of the World, 1212
 Research and Tomorrow's World: Today's (Dr. Vannevar Bush), 1212
 Research Awards: Lavarbume, for 1954, 1025
 Research Council of Israel: Special Publication No. 1, L. Furkas Memorial Volume (edited by Adalbert Furkas and Eugene P. Wigner), review by Prof. J. R. Partington, 930
 Research Development Corporation, National: Annual Report for 1952-53, 249
 Continuation of Borrowing Powers, 576
 Research Fellowship (J. H. Andrew) in Metallurgy in the University of Sheffield awarded to R. G. Ward, 981
 Research Fellowships: New Zealand National, 193
 United States (P.O.A.), awarded by the National Academy of Sciences to Dr. G. N. Lance and S. H. Parker, 151
 Research Fellowships in Schools of Pharmacy in Great Britain (Wellcome Trust), 195
 Research Fellowships in Tuberculosis: Dorothy Temple Cross (Medical Research Council), 245
 Research Film (Bulletin of the Research Film Committee of the International Scientific Film Association), 984
 Research Institution: The Independent, 599
 Research Planning and Policy, 649
 Research Scholarship (Aluminium Development Association), 896
 Research Scholarship offered by the Aluminium Development Association to the Institution of Structural Engineers, 1125
 Research Studentship in Geophysics (Royal Dutch-Shell Group of Oil Companies), 430
 Research Studentships tenable in Australia, Australian and United Kingdom Postgraduates (Commonwealth Scientific and Industrial Research Organization, the Department of Scientific and Industrial Research and the Agricultural Research Council), 429
 Research Studentships and Commonwealth Exhibitions (Trinity College, Cambridge), 195
 Research Tool: The Rocket as a, review by Prof. D. R. Bates, 697
 Research Work on the Chemistry of High Polymers: Fellowship for (to be established by the Dunlop Rubber Co. at the University of Birmingham), 195
 Research Workers and Students: Grants to (Department of Scientific and Industrial Research), 570
 Research and Clinical Laboratories: A Handbook of Colorimetric Chemical Analytical Methods for Industrial, developed for use with the Lovibond Comparator (Tintometer, Ltd.), review by J. King, 607
 Research and Scientific Services in East Africa, 1947-1956: A Survey of (Dr. E. B. Worthington), 65
 Researches in Physics: Recent, review by S. Wentroub, 921
 Resin (ion-exchange) Adsorption of Prostatic Phosphatase on (Dr. Hans G. Boman), 447
 Rosins (Cation-Exchange): Influence of, on Adenosine Triphosphate (N. A. Lund, F. S. M. Grylls and J. S. Harrison), 544
 Resistance to Fungal Attack: Chemical Basis of, 428
 Resistance to the Mamma Rust, *Puccinia polyspora* (Dr. H. H. Storey and A. K. Ryland), 778
 Resistance of Oats to *Ophiobolus graminis* (E. M. Turner), 428
 Resistant Houseflies: Metabolism of Gamma-Benzene Hexachloride in Susceptible and (F. J. Copennoorth), 1000
 Resistant Stocks of Parsnip: Parsnip Canker—Selection of (Donald E. Green and M. Ann Hewlett), 779
 Resolution (High): Carbon-14 β -Track Autoradiography of (Dr. M. C. Walters and R. Thaine), 1146
 Resolution (High) Electron Micrographs of Thin Tissue Sections (T. H. Hewlett and Dr. G. Eaves), 309
 Resolution in Nuclear Counter Amplifiers: Signal, Noise and (A. B. Gillespie), review by E. H. Cooke-Yarborough, 371
 Resolving Power of Photographic Lenses: Method for Determining (National Bureau of Standards, Circular 533), 1215
 Resonance: Electron, in Ionospheric Waves (C. O. Hines), 1087
 Paramagnetic, in Neutron-irradiated Diamond and Smoky Quartz (Dr. J. H. E. Griffiths, J. Owen and I. M. Ward), 439
 Resonance Absorption (Paramagnetic): A Study of Manganese Complexes by (Mildred Cohn and Jonathan Townsend), 1090
 Resonance Study: A Proton Magnetic, of the Hydration of Deoxyribonucleic Acid (Dr. Bertil Jacobson, Weston A. Anderson and James T. Arnold), 772
 Resources: World Population and (Prof. L. Dudley Stamp), 1218
 Respiration in Cauliflower Leaves: Relation of Molybdenum Status and Nitrogen Supply to (Dr. G. Ducet and Dr. E. J. Hewitt), 1141
 Respiratory Tissue of the Large Whales (Dr. S. Engel), 128
 Resaler, C., and others: Synthesis of Oxytocin, 1215
 Resurgent Asia: Western Science in, review by Lord Boyd Orr, 513
 Reconstitution of Hematins after Supercooling or Partial Crystallization at Body Temperatures below 0° C. (Dr. A. U. Smith, J. E. Lovelock and Dr. A. S. Parkee), 1136
 Rete: Studies of the Caroid, and its Associated Arteries (P. M. Daniel, J. D. K. Dawes and Marjorie M. L. Prichard), 759
 Retina (Frog): Density of Visual Pigment in (G. B. Arden), 360
 Reversible Inhibition of Pepsin by Polylysine (Dr. Ephraim Katchalski, Arish Berger and Hans Neumann), 998
 Reversible Photo-oxidation of a Cytochrome Pigment in Photosynthesizing *Rhodospirillum rubrum* (L. N. M. Duyens), 692
 Review of Scientific Instruments: Special Cosmotron issue, 344
 Reyle, K., and others: Hypoglycin A, β -Biologically Active Polypeptides from *Bignia saporida*, 356
 Reynolds, S. E.: Radio-Meteorology, 762
 Reynolds, W. L.: Fast Chemical Reactions, 1164
 Reynoldson, Dr. T. B., and others: A New Species of Freshwater Triched belonging to the Genus *Polysira*, 354
 Rheological Properties: Friction in relation to (British Society of Rheology Symposium on), 899
 Rheological Results and their Relations: Methods of Presenting (British Society of Rheology Symposium on), 156
 Rheology, British Society of Symposium on Methods of Presenting Rheological Results and their Relations, 156
 Conference on Rheology in Mechanical Engineering, 855
 Symposium on Friction in relation to Rheological Properties, 899
 Rheology of Foodstuffs, review by J. E. Caffyn, 1110
 Rheology in Mechanical Engineering (British Society of Rheology Conference on), 855
 Rhizomes: Horizontal Disposition of (N. G. Ball), 298
Rhizostoma pulmo: A Violet Pigment from the Mediterranean Medusa (Dr. A. Christomano), 875
 Rhoads, C. P., and others: Azaserine, a New Tumour-Inhibitory Substance—Studies with Crocker Mouse Sarcoma 180, 71
 Rhodes, D. H.: Appointed senior fisheries officer, Uganda, 112
 Rhodes, W. G.: Science Masters' Association—Annual Meeting at Oxford, 157
 Rhodesia University College: Appointment of Dr. W. Rollo as principal, 1022
 Rhodesia (Northern) and Nyasaland Joint Fisheries Research Organization: Appointment of G. Fryer and T. D. Iles as scientific officers, 112
 Rhodesian Shield: The Oldest Dated Minerals of the (Prof. Arthur Holmes), 612
Rhodospirillum rubrum: Reversible Photo-oxidation of a Cytochrome Pigment in Photosynthesizing (L. N. M. Duyens), 692
 Rhythms in *Periplaneta americana* L.: Diurnal (Janet E. Harker), 689
 Ribbands, C. R.: The Behaviour and Social Life of Honeybees, review by Dr. H. Kalmus, 96
 Ribonucleic Acid: Evidence for the Existence of Two Types of (Dr. Roy Markham, Dr. R. E. F. Matthews and Dr. J. D. Smith), 537
 Physical Studies on (Alexander Rich and J. D. Watson), 995
 Ribose in Animal Tissues: Synthesis of (Mary G. McGowan and Dr. F. H. Malpress), 212
 Ricardo, Sir Harry R.: The High-Speed Internal-Combustion Engine, fourth edition, review by D. B. Walbourn, 925
 Rich, A.: Structure of Proteins, 59
 Rich, A., and Watson, J. D.: Physical Studies on Ribonucleic Acid, 995
 Rich, Prof. A. R.: Elected a member of the National Academy of Sciences, Washington, 1173
 Richard, H. (Chole, J., and) Seismic Problems in Exploration Geophysics, 246
 Richards, F. J.: Elected a Fellow of the Royal Society, 568
 Richards, Dr. T.: Spoilage of Industrial Materials by Micro-organisms, 102
 Richards, T. C.: European Association of Exploration Geophysicists—Meeting in Milan, 246
 Richardson, Dr. E. G.: Sound, a Physical Text-Book, fifth edition, review, 1061
 The First and Second Viscosities of Fluids, 1209
 Richardson, Dr. E. G. (edited by): Technical Aspects of Sound, Vol. 1, Sonic Range and Airborne Sound, review by Dr. H. D. Parbrook, 1058
 Richardson, J. R.: High-Energy Accelerators, 1127
 Richmond's Dairy Chemistry, revised by Dr. J. G. Davis and F. J. Macdonald, fifth edition based on the previous revision by G. D. Elsdon and G. H. Walker, review by J. King, 513
 Rickets in Sheep (Dr. George Dunlop), 453
 Ricketts, Dr. C. R.: Dextran and its Applications, 237
 Ricketts, Dr. C. R. (Walton, Dr. Kenneth W., and) Anaphylactoid Response in Guinea Pigs to the Parenteral Administration of Sulphate Esters of High Molecular Weight of Dextran, 31
 Rideal, Sir Eric: Obituary of Prof. Marston T. Bogert, 851
 Ridout, M. S. (Billig, Dr. E., and) Transmission of Electrons and Holes across a Twin Boundary in Germanium, 496
 Ridale, P. S.: Death of, 240
 Rieck, Dr. G. D.: The new 'Norolco' Spectrometer, 21
 Rift Valley Fever Virus: Different-sized Infective Particles of (W. du T. Naudé, T. Madsen and Dr. A. Polson), 1051
 Rigg, Dr. Tyson, and others: Chemical Primary Processes in the Action of Ionizing Radiations on Water—Evidence from Experiments with Heavy Water, 1130
 Riley, Dr. D. P.: Structure of Proteins, 58
 Proteins and their Nature, review, 1059
 Riley, N. D.: A Provisional Check-List of the Butterflies of the Ethiopian Region, review, 98
 Rimington, Prof. C.: Elected a Fellow of the Royal Society, 568
 Rinaldi, Dr. L. M.: A Quantitative Method for Growing Animal Cells *in vitro*, 1134
 Rindner, L. (Olson, Dr. J. L., and) Magneto-Resistance of Copper to 150,000 Oersted at 4.2° K., 632
 Rung, J., and Wilcock, W. L.: Multilayer Dielectric Reflecting Films at Wavelengths between 4000 and 4600 Å., 994
 Rungsted, Dr. J.: Awarded a Scholarship by the Lady Tessa Memorial Trust for research on leukaemia and allied diseases, 1170
 Ripper, Dr. W. E.: Weed Control, 147
 Ritchie, Prof. A. D.: Science and Religion, review, 279
 The Works of George Berkeley, review, 416
 Ritchie, Comdr. G. S.: Awarded the Back Grant of the Royal Geographical Society, 569
 Ritchie, Comdr. G. S., and others: The Greatest Oceanic Sounding and the Topography of the Marianas Trench, 528
 Ritchie, J. N.: Appointed a member of the Agricultural Research Council, 807
 River Valley Projects: The Role of Silt and Sand in Multipurpose (Dr. N. K. Bose), 368
 Rivière, Dr. R. J. de la: Elected a member of the Rural Economy Section of the Paris Academy of Sciences, 1026
 Road Research in Great Britain, 961
 Road Research Board: Appointment of E. J. Powell as chairman, 476
 Robb, J. C.: Fast Chemical Reactions, 1163
 Roberts, C. W., and others: Synthesis of Oxytocin, 1215
 Roberts, D. W. A.: Invertebrate in the First Leaf of Wheat, 152
 Roberts, H. A.: Weed Control, 149
 Roberts, J. A., and others: Radio Evidence of the Ejection of Very Fast Particles from the Sun, 532
 Roberts, L. E. J.: Awarded a Commonwealth Fund Fellowship for study in the United States, 526
 Roberts, P. C.: Trends in Trade Union Organization, 383
 Robertson, Sir Dennis: Grant of 2,260 dollars from the Rockefeller Foundation of New York to visit American universities and research centres, 1080
 Robertson, G. W.: Awarded a Canadian Prize for 1953 of the Royal Meteorological Society, 807
 Robertson, J. A. L., and others: Some Physical Properties of Metallic Plutonium, 535
 Robertson, Prof. J. Montest: Organic Crystals and Molecules, review by Prof. K. Lonsdale, 964

- Robertson, Dr. Muriel: Recent Advances in Animal Morphogenesis, 520
 Robertson, R.: Gas Absorption, 1028
 Robertson, Dr. W. G. P.: Title of University Research Fellow in chemistry in the University of Birmingham conferred on, 338
 Robins, J. P.: Ovulation and Pregnancy Corpora Lutea in the Ovaries of the Humpback Whale, 201
 Robinson, Lady: Obituary by Prof. W. Baker, 566
 Robinson, F. A.: Antibiotics, review by Dr. A. M. Cook, 1157
 Robinson, Sir Robert: Cleavage of the 2:4-Dinitrophenylhydrazones of Ketones, 541
 Robinson, Dr. T. J.: Relationship of Oestrogen and Progesterone in Castrous Behaviour of the Ewe, 878
 Robson, M.: Appointed chief conservator of forests, Western Region, Nigeria, 570
 Roche, Dr. G. D., and others: Symbols for Fundamental Particles, 123
 Roche: Conference on High Energy Nuclear Physics: Proceedings of the Third Annual (compiled and edited by H. P. Noyes, M. Camac and W. D. Walker), review by Dr. E. Brecher, 607
 Rock Lobster: Occurrence and Distribution of Sarcoptes in the (L. Novelli and H. M. Schwartz), 450
 Rock-Magnetism (Prof. Takas Negata), review by Dr. J. M. Bruckshaw, 840
 Rock Magnetism and Polar Wandering (Dr. J. Hospers), 1183
 Rock Paintings by Miss M. E. Thompson: Gift of to the National Museum of Wales (Dr. F. J. North), 63
 Rock Terms: English (Dr. W. J. Arkell and Dr. S. I. Tolstoloff), review by V. A. Eyles, 7
 Glossary of Colloquial and Dialect, review by V. A. Eyles, 7
 Rockefeller, John D.: Industrialism and Philanthropy: Study in Power—(Allen Nevins), review by L. Farrer-Brown, 1009
 Rockefeller Fortune and its Utilization, review by L. Farrer-Brown, 1009
 Rockefeller Foundation: Gift of 5000 dollars to the University of Leeds for research in radiation chemistry, 570
 Grants to Institutions and persons in Great Britain, 1080
 Rockefeller Foundation Regional Virus Laboratory, Trinidad: Appointment of A. E. Green as senior British laboratory technician, 896
 Rockefeller Travelling Fellowships in Medicine (Medical Research Council), 245
 Rocks as a Research Tool, review by Prof. D. R. Bates, 697
 Rocks Research: High Altitude (Homer E. Newell, Jr.), review by Prof. D. R. Bates, 697
 Rocks, Minerals and Space Travel (Willy Ley), review by Prof. R. A. Rankin, 183
 Rocksey, V. D.: Radio-Meteorology, 763
 Rocks: Magnetic Characteristics of, review by Dr. J. M. Bruckshaw, 840
 Recent Developments in Great Britain in the Study of the Permanent Magnetization of (Discussion at the University of Birmingham), 1114
 Rocks (Igneous and Sedimentary): Natural Magnetization of (Dr. D. H. Griffiths and Dr. R. F. King), 1114
 Rocks (Metamorphic and Metasomatic): The Origin of (Prof. Hans Ramberg), review by Prof. H. H. Read, 913
 Rockwell: Direct Observation of Polygonization in (S. Amelinckx), 993
 Rodd, Dr. E. H. (edited by): Chemistry of Carbon Compounds, Vol. 1, Part B, Aliphatic Compounds, review, 231; Vol. 2, Part A, Aliphatic Compounds, review by Dr. C. Buchanan, 931
 Rodger, Alec: Health and Safety in Aviation, review, 654
 Roeder, Kenneth D. (edited by): Insect Physiology, review by Prof. V. B. Wigglesworth, 965
 Roels, Dr. H.: Mitosis and Deoxyribonucleic Acid Content of the Nucleus, 1039
 Royle, J.: Appointed scientific officer (entomologist), East Africa High Commission, 112
 Rogers, H.: Awarded the Hancock Medal for 1953 of the Institution of the Rubber Industry, 62
 Rogers, Dr. H. J. (Spensley, Dr. P. C., and): Enzyme Inhibition, 1190
 Rogers, R. R., and Rydell, J. P.: Effect of Germanium on the Transformation of White to Grey Tin, 290
 Rogosinski, Prof. W. W.: Elected a Fellow of the Royal Society, 568
 Volume and Integral, review by Dr. R. G. Cooke, 608
 Rohayem, H., and others: Influence of Egyptian Scorpion and Cobra Venoms on Mammalian Erythrocytes *in vitro*, 170
 Roller, Dr. Duane: Appointed editor of Science and the Scientific Monthly, 150; work of, 150
 Rollins, Read C., and others: Plant Genera, their Nature and Definition, review by Dr. W. B. Turrill, 908
 Rollo, Dr. W.: Appointed principal of Rhodesia University College, 1022; work of, 1022
 Rolt, F. H.: Engineering Dimensional Metrology, 293
 Romagnoli, Henri (Kühner, Robert, et): Flore analytique des Champignons supérieurs (Agarici, Boleti, Chytriales), review by Mrs. F. L. Balfour-Browne, 52
 Roman Gallery at the Grosvenor Museum, Chester, 291
 Romano—British Times: The Marshes of the Medway Estuary in (J. P. T. Burchell), 832
 Romer, Prof. Eugene: Obituary by Prof. L. Dudley Stamp, 753
 Room Temperature: Festigue Strength of Pure Tin at (Dr. E. C. Elwood and R. Duckett), 497
 Root Cells (Developing): Protactin in (C. Morgan and W. S. Reith), 1074
 Root Cells (Growing): Potassium Absorption by (R. Brown and P. M. Cartwright), 192
 Root Tissue Cytoplasm: Salt Uptake by (A. B. Hope), 617
 Roots (Excised): Growth of (J. C. Skinner and Dr. H. E. Street), 1214
 Roots (Excised Barley): Fixation of Carbon Dioxide by (L. W. Poel), 63
 Roots (Excised Tomato): Effects of α -(1-Naphthyl-Methylsulphide)-Propionic Acid on the Growth of (Dr. H. E. Street), 253
 Roots (Living): A New Cytochrome in (Prof. H. Lundegårdh), 939
 Roots of the Rosebay Willow-herb (Fireweed): Buds on the (Alan E. H. Emery), 546
 Roots and Shoots of *Brassica campestris* L. in relation to Vernalization: Anatomy of (S. C. Chakravarti), 407
 Ropke, Karl: Death of, 246
 Ropp, R. S. de, and others: Identity of Auxin in Normal Urine, 776
 Rose, Dr. H. E.: The Measurement of Particle Size in Very Fine Powders, review by Prof. Stanley G. Ward, 932
 Rose, Harry M., and others: Internal Structure in Virus Particles, 208
 Rose, O. S.: Varieties in relation to Crop Production, 199
 Rosebay Willow-herb (Fireweed): Buds on the Roots of the (Alan E. H. Emery), 546
 Rosen, B. et autres (écrit par): Tables de Constantes et données numériques, Vol. 5, Constantes sélectionnées; Atlas des longueurs d'onde caractéristiques des bandes d'émission et d'absorption des molécules diatomiques, review by Dr. A. G. Gaydon, 417
 Rosenbauer, Dr. N., and Willis, Dr. A. H.: Kinematics of Mechanisms, review by R. H. Macmillan, 924
 Rosenbach, O.: Gravity Problems in Exploration Geophysics, 246
 Rosenberg, L.: Radio-Meteorology, 764
 Rosenberg, Dr. Lawson L., and others: A New Glyceraldehyde Phosphate Dehydrogenase from Photosynthetic Tissues, 1132
 Rosenfeld, Prof. L.: Rationalism in Antiquity, 341
 Electrostatics et magnétostatique, review, 933
 Social Conditions and the Development of Science, 1102
 The First and Second Viscosities of Fluids, 1209
 Rosenthal, Dr. Harold L.: Composition of Bone and Muscle from the Lordotic and Normal Guppy, *Lebistes reticulatus*, 693
 Rosetta Disease of Groundnuts (A. C. Evans), 1242
 Rose, Dr. D. M.: Higher Education in China, 713
 Rose, K. B.: Appointed director of production in the Industrial Group of the Department of Atomic Energy at Rusey, 807
 Rose Institute of Tropical Hygiene: Course in Tropical Hygiene for Laymen, 476
 Rosser, Prof. J. Berkeley: Logic for Mathematicians, review by Prof. H. T. H. Piaggio, 925
 Rosin, Prof. B., and others: Symbols for Fundamental Particles, 123
 Rositter, J. R.: Analysis of the 1953 Storm Surge in the North Sea, 861
 Rosman, P. O.: Radio-Meteorology, 763
 Rotation of the Earth: Effect of Movement of Surface Masses on the (Andrew Young), 617
 Glacial Eustasy and the (Andrew Young), 19
 Rotational Analysis of the Columbium Oxide Bands (K. Suryanarayana Rao), 1240
 Rothblat, Prof. J.: Obituary of Prof. Stefan Phienkowski, 105
 Rothblat, Prof. J., and others: Range-Energy Relation in Nuclear Track Emulsions for Protons of Energy up to 21 MeV., 1180
 Roth, W. L.: Spiroidal Crystals of Zinc Sulphide, 38
 Rothbaum, H. P.: Awarded a New Zealand National Research Fellowship, 193
 Rothschild, Lord, and Barnes, H.: Osmotic Pressure of Bull Sperm Diluents, 636
 Rothschild, Miriam (Hopkins, G. H. E., and): An Illustrated Catalogue of the Rothschild Collection of Fleas (Siphonaptera) in the British Museum (Natural History), Vol. 1, Tungidae and Pulicidae, review by G. P. Holland, 1203
 Rothschild, Dr. S.: Luminescence of Inorganic Phosphors, 1077
 Rothschild Collection of Fleas (Siphonaptera) in the British Museum (Natural History): An Illustrated Catalogue of the (G. H. E. Hopkins and Miriam Rothschild), Vol. 1, Tungidae and Pulicidae, review by G. P. Holland, 1203
 Rouelle and Chemistry in France (Dr. Douglas McKee), 429
 Roughton, F. J. W.: Fast Chemical Reactions, 1162
 Rous, Dr. F. Peyton: Honorary Fellowship of the Weizmann Institute of Science conferred on, 67
 Rovina, A. D. (Bunt, J. S., and): Oxygen Uptake and Carbon Dioxide Evolution of Heat-sterilized Soil, 1242
 Rowett Research Institute: Collected Papers of the, Vol. 10, 1124
 Rowlands, D. G.: Control of Mitotic Activity, 828
 Roy, A. K.: Elected a Fellow of the National Institute of Sciences of India, 474
 Roy, Dr. S. C. (Sen, Dr. M. K., and): Structures of Native and Mercaptized Celluloses, 298
 Royal Aeronautical Society: Awards, 852
 Royal Air Force Coastal Command (National Institute of Oceanography and the): Investigation of Oil Pollution by Drift Envelopes, 108
 Royal Anthropological Institute: Public Lectures on the English Heritage, 339
 Royal Astronomical Society: Gold Medal awarded to Dr. Walter W. Bende, 112
 Geophysical Discussion on Airborne Magnetic Surveys, 281
 Election of Officers for 1954-55, 338
 Redring Presidential Address (Prof. H. Dingle), 574
 Election of Associates, 714
 Royal Astronomical Society and the British Glaciological Society: Geophysical Discussion on Changes in World Glaciation, 1206
 Royal Cancer Hospital: Title of professor of cytogenetics in the University of London conferred on Prof. P. C. Koller, 615
 Royal College of Science: Research Activities carried out during 1950, 1951 and 1952, 758
 Royal Commission for the Exhibition of 1851: Awards for 1954, 1216
 Royal Dutch-Shell Group of Oil Companies: Research Studentship in Geophysics, 430
 Royal Finnish Academy of Sciences: Election of Prof. A. C. Frazer as an associate member, 292
 Royal Free Hospital School of Medicine: Appointment of Dr. D. N. Baron to University of London readership in chemical pathology, 619
 Appointment of Dr. Eleanor J. Zalms to the University of London readership in pharmacology, 619
 Appointment of Dr. C. B. B. Downman to the University of London readership in physiology, 1171
 Royal Geographical Society: Awards for 1954, 569
 Royal Institute of Chemistry: Easterfield Medal of the New Zealand Section, 855
 Royal Institute of Chemistry (Manchester Section), and others: Symposium on Dynamic Stereochemistry, 194
 Royal Institute of Chemistry (Scottish Section): Symposium on the Chemistry and Industrial Applications of Cellulose, 111, 896
 Royal Institute of International Affairs: Grant of 31,500 dollars from the Rockefeller Foundation of New York in support of a study of Race Relations in Central Africa, 1080
 Grant of 3,100 dollars from the Rockefeller Foundation of New York to enable Miss Lois Simpson and Miss Helen G. Liddell to visit the United States and Canada, 1080
 Royal Institution: Election of Officers, 855
 Royal Institution of Engineers of the Netherlands (Chemical Engineering Group), and others: Conference on Unit Processes of Oxidation, 245, 571
 Royal Irish Academy: Celebration of the Centenary of the publication of the Laws of Thought by George Boole, 1212

- Royal Meteorological Society: Napier Shaw Memorial Prize, 473
Awards, 807
Meeting in the Department of Natural Philosophy, The University, Edinburgh, 1026
o Symposium on the Upper Atmosphere, 1026
Symposium on Meteorology and Scottish Agriculture, 1026
- Royal Military College of Science, Shrivenham: Appointment of Prof. C. J. Tranter as Beshforth professor of mathematical physics, 241
- Royal Netherlands Chemical Society (Section for Chemical Technology), and others: Conference on Unit Processes of Oxidation, 245, 571
- Royal Observatory, Cape of Good Hope: Report for 1952, 437
- Royal Photographic Society: Exhibition of Underwater Photography, 855
- Royal Photographic Society (Scientific and Technical Group): Symposium on Microradiography and Autoradiography, 387
- Royal Sanitary Institute: Exhibition on Dry Rot and Woodworm to be opened by Sir David Eccles, 855
- Royal School of Mines, London: Mineral Dressing at the (E. J. Pryor), 565
Summer School in Mineral Dressing to be held by the Imperial College of Science and Technology in the Bessemer Laboratory, 571
- Royal Scottish Forestry Society: To issue four special numbers of *Scottish Forestry* as a Centenary Volume, 765
- Royal Scottish Museum: Robert Jameson and the (V. A. Eyles), 904
- Royal Society of Arts (Kenneth W. Luckhurst), 12
Bicentenary Celebrations (Kenneth W. Luckhurst), 656
- Royal Society of Arts, and others: Establishment of a joint Science and Industry Committee, 1072
- Royal Society of Edinburgh: Neill Prize for 1951-53 awarded to Prof. J. K. Charlesworth, 430
Election of new Fellows, 474
Keith Prize for the period 1951-53 awarded to Dr. D. E. Rutherford, 855
- Royal Society of London: Lectures during 1954, 385
Year Book for 1954, 524
New Fellows of the, 567
Age of Election to the (Prof. A. V. Hill), 758
New Foreign Members, 852, 977
Appointment of Dr. E. Marsden as Rutherford Memorial Lecturer for 1954, 1026
Appointment of D. M. Brink as a Rutherford Scholar, 1026
Discussion on the First and Second Viscosities of Fluids, 1209
Depository of Unpublished Mathematical Tables, 1221
- Royal Society and the Nuffield Foundation: Bursaries for research in Commonwealth Countries, 151
- Royal Society of Medicine (Endocrinological Section), (Society for Endocrinology and the): Symposium on the Technique and Significance of Estrogen Determinations, 195
- Royal Society of New Zealand: Eighth New Zealand Science Congress, 20
- Royal Technical College, Salford: Postgraduate Course on Chromatography, 339
- Royal Veterinary College: Title of professor of veterinary bacteriology in the University of London conferred on Dr. Reginald Lovell, 64
Appointment of Prof. J. McCunn as acting principal, 1171
- Royer, Prof. Louis: Elected a correspondent for the Mineralogical Section of the Paris Academy of Sciences, 244
- Ruanda-Urundi: *Flore du Congo Belge et du*, Vol. 4, Spermatophytes, Papilionaceae I, 854
- Rubber (Crepe): Microflora of (J. N. Turner and M. E. Kennedy), 506
Rubber in Compression: Effect of Previous Stress-Strain History on the Dynamic Hysteresis Loop for (D. M. Davies and H. McCallion), 262
Rubber in *Herposiphonia*: Effect of Mineral Status on the Concentration of (Dr. E. W. Bolle-Jones), 690
Rubber Fillers (Reinforcing): Free-Radical Activity of (Dr. V. A. Garten), 977
- Rubber Industry, Institution of the: Medal Awards for 1953, 62
Rubber Research Institute of Malaya: Work of the Botanical Division, 296
Rubner, Max (1854-1932), 1023
- Rugby School Natural History Society: Report for 1953, 758
- Rumford, F.: Gas Absorption, 1028
- Ruminant-like Digestion in a Marsupial (R. J. Moir, M. Somers, G. Sherman and Prof. H. Waring), 269
- Rumney, Jay, and Maier, Joseph: *The Science of Society*, second edition, review by Prof. T. S. Simey, 702
- Runciman, W. A.: Luminescence of Inorganic Phosphors, 1078
- Runcorn, Dr. S. K.: Airborne Magnetic Surveys, 281
Recent Developments in Great Britain in the Study of the Permanent Magnetization of Rocks, 1115
- Rural Wales, Council for the Preservation of: Annual Report for 1952-53, 1024
- Rushbrooke, Prof. G. S.: Elected a Fellow of the Royal Society of Edinburgh, 474
- Rushton, Dr. W. A. H., and Cohen, R. D.: Visual Purple Level and the Course of Dark Adaptation, 301
- Russell, Sir John: The Early Days of Agriculture, review, 916
- Russell, Rosemary (Lockley, R. M., and): Bird-Ringing, review by Dr. Bruce Campbell, 906
- Russell, Dr. W. Ritchie: Reactions of the Human Body to Injury, 1174
- Russian and other Slavonic Languages: Investigations in Physics published in, 384
- Russian Progress in Electron Diffraction, review by Dr. H. Lipson, 919
- Rust Fungus in India: Dissemination of (Prof. Mahata), 665
- Rust Fungus: A Systematic (B. P. Mendel), 570
- Rutgers University: Some Conjugated Proteins, a Symposium (Six lectures presented at the Ninth Annual Conference on Protein Metabolism held at the Bureau of Biological Research, January 30-31, 1953), edited by William E. Cole, review, 141
- Rutherford, Lady: Death of, 195
- Rutherford, Dr. D. E.: Awarded the Keith Prize for the period 1951-53 of the Royal Society of Edinburgh, 855
- Rutan (Sterility Hormone): An Antagonist of the, in the Green Alga *Chlamydomonas reinhardtii*: Ombuicide-7,4-Dimethyl-rutin (Dr. Franz Morawus and Dr. Venando Deslofeu), 218
- Rutledge, Dr. Harold: Obituary by Prof. Arthur Holmes, 851
- Ruttenberg, Dr. Franz: Fundamentals of Limnology, translated by Dr. D. G. Frey and F. E. J. Fry, review by H. C. Gilson, 652
- Rusd, Prof. Johan T.: Vertebrates without Erythrocytes and Blood Pigment, 848
- Ryder, Albert, and others: Azaserine, a New Tumour-Inhibitory Substance—isolation and Characterization of Azaserine, 72
- Rydon, Prof. H. N.: The Faraday Society—The First Fifty Years, 1903-1953, review, 936
- Rygaard, Dr. J.: Awarded a Scholarship by the Lady Tata Memorial Trust for research on leukaemia and allied diseases, 1170
- Ryland, A. K. (Storey, Dr. H. H., and): Resistance to the Mazze Rust, *Puccinia polysora*, 778
- SACCHAROMYCES cerevisiae** Long-Term Adaptation to the Fermentation of Galactose in (David D. Pittman and Prof. Carl C. Lindgren), 408

 Schmidt, Dr. W. J. : Elected a Foreign Honorary Member of the American Academy of Arts and Sciences, 978
 Schmitz, F. O. : Structure of Proteins, 58
 Schneider, Dr. H. : Appointed lecturer in pure mathematics at Queen's University, Belfast, 714
 Scholar : The Happy (Dr. Charles Singer), 1027
 The Travelling, and International Understanding, 1
 The Travelling, in Europe—British Council Activities, 528
 Scholars (Refugees) : The Rescue and Achievement of (Norman Bentwich), review by Dr. H. E. Wimpers, 1201
 Scholars and Scientists of 1933-52 : The Displaced, review by Dr. H. E. Wimpers, 1201
 Scholarship : Research (Aluminium Development Association), 896
 Research (Offered by the Aluminium Development Association to the Institution of Structural Engineers), 1125
 Tuition (Colorado School of Mines), 526
 Scholarship in Textile Technology : Cotton Industry War Memorial (Textile Institute), 657
 Scholarship Grants for Education in Plastics (Plastics Industry Education Fund), 1170
 Scholarship Scheme (Marshall) : Proposed Arrangements for the Administration of the, 1
 Scholarships (Ministry of Agriculture and Fisheries), 195 ; (Mood Nickel Fellowships Committee), 339
 Overseas (Royal Commission for the Exhibition of 1851 Awards for 1954), 1216
 Postgraduate Agricultural (Ministry of Agriculture and Fisheries), 429
 Scholarships in Agricultural Subjects : Postgraduate (Ministry of Agriculture and Fisheries and the Department of Agriculture for Scotland), 385
 Scholarships to British workers in Medical Science offered by the Medical Research Council on behalf of the Centre National de la Recherche Scientifique, 339
 Scholarships in Civil Engineering (Gift of £500 from the Cement and Concrete Association to the University of Leeds for), 570
 Scholarships in Concrete Technology (Gift of £200 a year for seven years from Wm. Alrey and Son (Leeds), Ltd., to the University of Leeds for), 570
 Scholarships in Personnel Management (Institute of Personnel Management), 110
 Scholarships for Study Abroad during 1954-55 (British Council Booklet on), 93
 Scholarships and Bursaries in Dentistry, Biology and the Social Sciences : Fellowships, (Nuffield Foundation), 338
 Scholarships or Fellowships for research on Diseases of the Blood : Grants, (Lady Tata Memorial Fund), 245
 Scholarships : A, 1074
 Scholer, Dr. George, and Weiss, Dr. Joseph : Formation of Acetyl Phosphate by the Action of X-Rays on Monoethyl Phosphoric Acid in Aqueous Solution, 267
 School, Prof. B. P. J. : Appointed deputy director of the Atomic Energy Research Establishment, Harwell, 896
 School to University : From (R. R. Dale), 1056
 School Course in Mechanics (A. J. Bull), Part 2, review, 515
 Schools : Medical, of the World, review, 52
 Science Teachers in, 177, 242 ; (W. G. Marshall), 770 ; (Stanley Conway), 770
 Shortage of Science Teachers in (Federation of British Industries Conference on), 196 ; Formation of a Committee on the (Federation of British Industries), 712
 Schools (Medical) : World Directory of, review, 52
 Schott, G. : Fast Chemical Reactions, 1163
 Schore, D. J. : Changes in World Glaciation, 1207
 Schrödinger, Prof. E. : Measurement of Length and Angle in Quantum Mechanics, 442
 Schrödinger, Prof. E., and others : Scientific Papers presented to Max Born on his retirement from the Tait Chair of Natural Philosophy in the University of Edinburgh, review by D.R.H., 327
 Schuster, Robert D. (Hart, Harold, and) : A Short Course in Organic Chemistry, review by F. Powles, 929
 Schulman, Dr. J. H. : Luminescence of Inorganic Phosphors, 1077
 Schurz, Dr. Josef : Sulfate-Phosphoric Acid Solutions, 952
 Schwartz, H. M. (Novell, L. and) : Occurrence and Distribution of Sarcosine in the Rock Lobster, 450
 Science : Bibliography and the History of (V. A. Eyles), 525
 Earth (Gustav L. Fletcher and Caleb Wroe Wolfe), third edition, review by D. W. Bishop, 928
 Essays on the Social History of (edited by S. Lilley), review by Prof. Herbert Dingle, 791, 1102 ; (Prof. L. Rosenfeld), 1102
 Explorations in (Videler Kumpffert), 1199
 Graduate Teachers of Mathematics and : a Report of the National Advisory Council on the Training and Supply of Teachers (Ministry of Education), 177, 242
 History of, review by Dr. A. R. Hall, 372
 Impact of, on Society (Dr. A. King), 758 ; (Dr. C. Sarbie), 758 ; (R. T. Edisson), 758 ; (Dr. Armando Cortes), 758
 Industry and, a Study of their Relationship based on a Survey of Firms in the Greater Manchester Area, 1950-1953 (Manchester Joint Research Council), 741
 From Magnifying Glass to Eye of (National Museum for the History of Science, Leyden, Exhibition), 1171
 Philosophical Analysis of 'Objective' Probability in, review by Prof. Jerzy Neyman, 603
 Poetry and (P.E.N. Club Discussion on), 113 ; (Prof. H. Levy), 506
 Shortage of Graduate Teachers of, 196
 Social Conditions and the Development of, review by Prof. Herbert Dingle, 791, 1102 ; (Prof. L. Rosenfeld), 1102
 Swedish, since 1850, review, 50
 Swedish Men of, 1850-1950 (edited and with an Introduction by Prof. Sten Lindroth), translated from the Swedish by Burnett Anderson, review, 50
 Utilization of, by Industry, 741
 Western, in Assuring Asia, review by Lord Boyd Orr, 513
 Science (Exact) : The Development of Meteorology as an (Dr. O. G. Sutton), 1112
 Science (Experimental) : Robert Grosscrosse and the Origins of, 1100-1700 (A. C. Crombie), review by Prof. E. J. Dijksterhuis, 138
 Science (Medieval) : Grosscrosse and, review by Prof. E. J. Dijksterhuis, 138
 Science (Modern) : The Logic of (Prof. J. R. Kantor), review by Prof. J. H. Woodger, 912
 Science (Pure and Applied) : The Organization of (Prof. M. Polanyi), 853
 Science (Social) : The Tools of (John Mage), review by Prof. T. S. Simey, 1010
 Science in the U.S.A. for the Year ending June 1953 : BCSO Review of (British Commonwealth Scientific Office, North America), 900
 Science, British Society for the History of : Formation of a Northern Section of the Philosophy of Science Group, 152
 Inaugural Meeting of the Northern Section of the Philosophy of Science Group (Dr. W. Mays), 341
 Science in Criminology, review by Dr. Keith Simpson, 745
 Science in Education and Industry, 367
 Science of Design : The Art and, review by D. B. Welbourn, 925
 Science of Pharmacology (Prof. J. H. Gaddum), 14
 Science of Society (Jay Rummy and Joseph Maser), second edition, review by Prof. T. S. Simey, 702
 Science and Agriculture, Department of, Barbados : Appointment of J. Bolton as chemist, 112
 Science and Cosmology (Prof. H. Dingle), 574
 Science and Foreign Relations in the United States, 192
 Science and Industry—the Pattern of the Future (Sir Harold Hartley), 1126
 Science and Industry in the Nineteenth Century (Prof. J. D. Bernal), review by R. Brightman, 139
 Science and Industry Committee : Joint (established by the Royal Society of Arts, the British Association for the Advancement of Science, and the Nuffield Foundation), 1072
 Science, Medicine and History, Essays on the Evolution of Scientific Thought and Medical Practice written in honour of Charles Singer (collected and edited by Dr. E. Ashworth Underwood), review by Prof. E. N. da C. Andrade, 651
 Science and Religion, review by Prof. A. D. Ritchie, 279
 Some Aspects of the Conflict between (Prof. H. H. Price), 152
 Science and the Scientific Monthly : Appointment of Dr. Duane Roller as Editor, 150
 Science and the Social Order (Bernard Barber), review by R. Brightman, 5
 Science Congress : Eighth New Zealand (Royal Society of New Zealand), 20
 Science Congress : Second (Pan Indian Ocean Science Association), 667
 Science Masters' Association : Annual Meeting at Oxford (W. G. Rhodes), 157
 Science Museum, London : Astronomy Mural by A. R. Thomson, 979
 New Gallery devoted to Gas Manufacture, its Distribution and its By-Products opened by the Marquess of Salisbury, 1024
 Science Teachers in Schools, 177, 242 ; (W. G. Marshall), 770 ; (Stanley Conway), 770
 Shortage of (Federation of British Industries Conference on), 196
 Formation of a Committee on the Shortage of (Federation of British Industries), 712
 Sciences : A History of the, Main Currents of Scientific Thought (Dr. S. F. Mason), review by Dr. A. R. Hall, 372
 Sciences (Social) : Fellowships, Scholarships and Bursaries in Dentistry, Biology and the (Nuffield Foundation), 338
 Framework of the, review by Prof. T. S. Simey, 1010
 Scientific Appraisal of Singing Voices (Dr. Fritz Winkel), 574
 Scientific Centenaries in 1954 (Joan M. Eyles), 9
 Scientific Council for Africa South of the Sahara : Publication No. 4, Maps of Africa South of the Sahara, 428
 Report for 1952-53, 1129
 Scientific Explanation (Richard Bevan Brathwaite), review by Prof. Jerzy Neyman, 603
 Scientific Film Association, International : Research Film (Bulletin of the Research Film Committee of the), 984
 Scientific Ideas : Birth and Development of, review by R. Brightman, 139
 Scientific Instrument Manufacturers' Association : Resignation of A. G. Peacock as secretary, 526, 807
 Appointment of E. D. Hart as deputy director, 807
 Appointment of Miss G. E. Moss as secretary, 807
 Scientific Instruments, Journal of (edited by Dr. H. R. Lang), Vol. 30, 1953, review, 1061
 Scientific Instruments, Review of : Special Cosmotron Issue, 344
 Scientific Instruments and Apparatus (Physical Society's Thirty-eighth Annual Exhibition of), 153, 525
 Handbook of (Physical Society), 618
 Scientific Investigation : The Art of (Prof. W. I. B. Beveridge), second edition, review by Dr. A. S. Parkes, 936
 Scientific Investigations in the Christie Case : Medical and (Dr. Francis E. Camps), review by Dr. Keith Simpson, 745
 Scientific Meeting : Simultaneous Translation at a, 1213
 Scientific Men visiting Britain : Offer of help to (Horse Shoe Club, the Ciba Foundation, and the Society for Visiting Scientists), 108
 Scientific Methods of Preventing Crime (Olaf Kunberg), 1124
 Scientific Monthly : Science and the (Appointment of Dr. Duane Roller as Editor), 150
 Scientific Papers presented to Max Born on his retirement from the Tait Chair of Natural Philosophy in the University of Edinburgh (Sir Edward Appleton, David Bohm, Louis de Broglie, Richard Courant, Albert Einstein, Pascual Jordan, Th. V. Kármán and S. S. Penner, Alfred Landé, Erwin Schrödinger, Hermann Weyl), review by D.R.H., 327
 Scientific Problem : Some Thoughts on the Evolution of a (Sir Cyril Hinshelwood), 157
 Scientific Progress : Latin American Contributions to, Report 3, Parasitology 1949-50 (Unesco Science Co-operation Office for Latin America), 644
 Scientific Radio Union, International (American National Groups of Commission II), and others : Symposium on Radio-Meteorology, 761
 Scientific Requirements of Pakistan, 337
 Scientific Research in the East (Dr. M. Razuddin Siddiqi), 337
 Scientific Research and Exposition, 1199
 Scientific Research and Industry in Britain, 787
 Scientific Results : Failure to Publish (Prof. P. A. Buxton), 410 ; (Dr. W. J. Hall), 784

- Scientific Services in East Africa, 1947-1956 : A Survey of Research and (Dr. E. B. Worthington), 65
- Scientific Societies : Natural History of Learned and (Prof. John Cohen, C. E. M. Hansel and Edith F. May), 328, 714
- Scientific Societies, South-Eastern Union of : Fifty-ninth Annual Congress, 854
- Scientific Study of Human Work In Industry (Ergonomics Research Society Conference on), 983
- Scientific Unions, International Council of (Joint Commission on Electron Microscopy) : International Conference on Electron Microscopy, 194, 291
- Scientific Unions, International Council of (Joint Committee on Oceanography) : Publication of a new journal, *Deep-Sea Research*, 527
- Scientific Unions, International Council of (American National Groups of the Joint Commission on Radio-Meteorology), and others : Symposium on Radio-Meteorology, 761
- Scientific Workers : Survey on Visas to the United States for (Federation of American Scientists), 427
- Scientific World : The Place of Religion In the, review by the Very Rev. Dr. W. R. Matthews, 512
- Scientific and Industrial Instruments : A Manual of, review by Dr. C. A. Taylor, 464
- Scientific and Industrial Research, Advisory Council for : Appointment of Sir Hugh Beaver as chairman, 1171
- Scientific and Industrial Research, Central Laboratories for (Hyderabad) : Opening Ceremony, 422
- Scientific and Industrial Research, Council for (New Delhi) : The Wealth of India, Raw Materials, Vol. 3, D-E, review by Sir John Simonsen, 142
- Scientific and Industrial Research, Department of : National Building Series, Special Report No. 21, Productivity in House-Building, Second Report, 69
- Report of the Radio Research Board with the Report of the Director of Radio Research for the Year 1952, 158
- Report of the Forest Products Research Board with the Report of the Director of Forest Products, for the Year 1952, 201
- Recruitment of Dr. Ezer Griffiths as a senior principal scientific officer in the Physics Division of the National Physical Laboratory, 289
- Appointment of Dr. R. W. Powell as a senior principal scientific officer in the Physics Division of the National Physical Laboratory, 290
- National Physical Laboratory, in co-operation with the Mechanical Engineering Research Laboratory, East Kilbride, Symposium on Engineering Dimensional Metrology, 293
- Report of the Water Pollution Research Board with the Report of the Director of Water Pollution Research for the Year 1952, 343
- Appointment of Sir Henry Manzoni as chairman of the Building Research Board, 476
- Appointment of Dr. R. Holroyd as chairman of the Food Investigation Board, 476
- Appointment of Sir Walter Drummond as chairman of the Geological Survey Board, 476
- Appointment of E. J. Powell as chairman of the Road Research Board, 476
- Grants to Research Workers and Students, 570
- Forest Products Research Laboratory Bulletin No. 26, An Atlas of End-Grain Photomicrographs for the Identification of Hardwoods, 624
- National Physical Laboratory, Notes on Applied Science No. 4, Measurement of Humidity, 712
- Symposium at the National Physical Laboratory on Creep and Fracture of Metals at High Temperatures, 714
- Report for the Year 1952 of the National Physical Laboratory, 717
- Report for the Year 1952-53, 797
- Extension to the Metallurgy Division of the National Physical Laboratory (H. A. Slemen), 808
- New Surge Generator at the National Physical Laboratory (R. S. J. Spilbury), 850
- New Building for the Radio Research Station, 894
- National Physical Laboratory, Teddington—Open Day, 1069
- Scientific and Industrial Research, Department of, and others : Australian and United Kingdom Postgraduate Research Studentships available in Australia, 429
- Scientific and Industrial Research, Department of, New Zealand : Appointment of Dr. R. M. Williams as director of the Applied Mathematics Laboratory, 619
- Scientific and Technical Books : Recent, Supp. vii, January 30 ; Supp. viii, February 27 ; Supp. viii, March 27 ; Supp. viii, April 24 ; Supp. viii, May 29 ; Supp. viii, June 26

- Scottish Home Department : Report of the Scottish Peat Committee, 1174
- Scottish Museum (Royal) : Robert Jamieson and the (V. A. Eyles), 904
- Scottish Peat Committee : Report of the (Scottish Home Department), 1174
- Scrags, E. B. : Weed Control, 148
- Screwing : Metallic Transfer in, and Its Significance In Bone Surgery (Dr. F. P. Bowden and J. B. P. Williamson, and P. Gowans Lung), 520
- Screws (Stainless Steel) : Clinical and Metallurgical Observations on the Corrosion of, used In Orthopaedic Surgery (J. K. Wright and Dr. H. J. Axon), 1186 ; (Dr. F. P. Bowden and J. B. P. Williamson), 1187 ; (P. Gowans Lung), 1187
- Sea : International Conference on the Prevention of Oil Pollution of the, 979
- Sea Anemone : Effects of Trypsin and Thiolglycolate upon the Nematocysts of the (T. M. Yanagita and Tuneyo Wada), 171
- Sea Urchins : Electrical Method of Determining the Sex of (Ethel Browne Harvey), 86
- Sea Water (Woods Hole) : Cation Analysis of (D. R. Shanklin), 82
- Seaborg, Prof. G. T. : Element 99, 290
- Seaborg, Prof. G. T., and collaborators : Production of Element 100, 757
- Seaborn, Miss J. E. (Davis, H. M., and) : Awarded a Radio Industry Council Premium for Technical Writing, 384
- Seal (Harbour), *Phoca vitulina* L. : Delayed Implantation in the (H. D. Fisher), 879
- Sears, J. E. : Engineering Dimensional Metrology, 293
- Seaweed Research, Institute of : Proceedings of the First International Seaweed Symposium, 193
- Seaweed Symposium : Proceedings of the First International (Institute of Seaweed Research), 193
- Secrecy and Security In Atomic Research, 835
- Security in Atomic Research : Secrecy and, 835
- Security Problems : Academic Freedom and, 695
- Sedimentary Rocks : Natural Magnetization of Igneous and (Dr. D. H. Griffiths and Dr. R. F. King), 1114
- Sedimentation : Calcareous Flagellates In Deep-Sea Fertility and (F. Bernard), 528
- Sediments (Deep-Sea) : Thorium Determination In (Dr. E. Picciotto and S. Wilgum), 632
- Seed (Stored) : Abnormalities of (B. J. Harrison and Dr. J. McLeish), 593
- Seed Production, Testing and Distribution in European Countries (Organization for European Economic Co-operation, Technical Assistance Mission No. 106), 1030
- Seed Treatment : Control of Cockchafer Grubs by (Dr. S. A. J. Tarr), 1052
- Thermo-chemical (I. A. M. Crutcher), 217
- Seedling Blight of Maize : Influence of Temperature and Soil Water Content on the (John L. Harper), 391
- Seedling Resistance and Maturity-Plant Susceptibility of Wheat to *Puccinia graminis* found In Kenya (A. D. S. Duff), 779
- Seeds of *Atropa belladonna* : Alkaloids In Germinating (Dr. P. Reipouts van Hagen), 692
- Segments : A Trough for Paper Chromatography consisting of (Dr. Ch. Wunderly), 267
- Seismic Prospecting : Early Arrivals In (Dr. F. F. Evbion), 1047
- Seismology : Bibliography of (W. G. Milne), Vol. 14, Nos. 9-12, 713
- Selection of University Students, 91, 1055
- Selen, A. M. (Colledan, V., and) : Seismic Problems In Exploration Geophysics, 246
- Selen, A. M. (Martini, E., and) : Seismic Problems In Exploration Geophysics, 246
- Selenite : Faked Nature of an Insect Wing in a specimen of (H. F. Whitworth), 664
- Selényi, Prof. Paul : Obituary by Dr. Francis Korday, 1071
- Sellman, G. : Elected president of the British Glaciological Society for 1954, 384
- Changes In World Glaciation, 1206
- Seligmann, Dr. M. : Awarded a part-time Scholarship and Grant by the Lady Teta Memorial Trust for research on leukaemia and allied diseases, 1170
- Selman, Dr. I. W., and others : Liberation of Boron from 'Pyrex' and 'Hyal' Glass In relation to Plant Growth in Water Culture, 957
- Semen Diluents in the Artificial Insemination of Cattle (R. C. Campbell and J. Edwards), 637
- Semen Diluents (Bull) : Osmotic Pressure of (Lord Rothschild and H. Barnes), 636
- Semiconductance In Molecular Single Crystals : Photo- and (D. J. Carnwell, J. Ferguson and L. E. Lyons), 736
- Semiconductor : Application of the Hall Effect In, to the Measurement of Power In an Electromagnetic Field (Prof. H. M. Barlow), 41
- Semiconductors : International Conference on (Netherlands Physical Society, the International Union of Pure and Applied Physics and Unesco), 338
- Semimicro Organic Chemistry : Apparatus for (Dr. S. H. Harper), 715
- Sen, Dr. M. K., and Roy, Dr. S. C. : Structures of Native and Mercaptized Celluloses, 298
- Sen, Dr. R. N. : Elected a Fellow of the National Institute of Sciences of India, 474
- Sen Gupta, M. R. : Elected a Fellow of the National Institute of Sciences of India, 474

- Tomlin Medal of the Worshipful Company of Clockmakers, 807
- Tools of Social Science (John Madge), *review* by Prof. T. S. Simay, 1010
- Topically Applied Mechanisms: Utilization of, by the Guinea Pig (Dr. L. J. Edwards), 1042
- Topographical Features (Deep-Sea): Nomenclature as applied to (Dr. J. D. H. Whelan and C. D. Ovey), 527
- Topography: Trans-Atlantic Profile of Total Magnetic Intensity and, from Dakar to Barbados (B. C. Heezen, M. Ewing and E. T. Miller), 528
- Topography of the Marianas Trench: The Greatest Oceanic Sounding and the (Dr. T. F. Gaskell, J. C. Swallow and Comdr. G. S. Ritchie), 528
- Topology: General (Prof. Wladyslaw Sierpinski), translated by C. Cecilia Krieger, second edition, *review* by Dr. R. G. Cooke, 418
- Topology (Algebraic): Foundations of (Samuel Eilenberg and Norman Steenrod), *review* by Dr. R. G. Cooke, 934
- Tornaboni, Dr. H.: Engineering Dimensional Metrology, 293
- Toulmin, Dr. S. E.: Appointed to the chair of philosophy in the University of Leeds, 1123, work of, 1123
- Townsend, Jonathan (Cohn, Mildred, and): A Study of Manganous Complexes by Paramagnetic Resonance Absorption, 1090
- Townsend, W. N.: Lime in Agriculture, *review*, 6
- Toxic Chemicals in Agriculture and their Effect on Foodstuffs (Dr. Francis Aylward), 1063
- Toxic Nitro Compound from *Streptomyces tholozani* (Yoshimasa Hirata, Kunio Okuhara and Takayuki Naitō), 1101
- Toxicity of Industrial Organic Solvents (Dr. Ethel Browning), revised edition, *review*, 655
- Toxicology: Paper Chromatographic Examination of the Alkaloid Extract in (Dr. A. S. Curry and H. Powell), 1143
- Toxin paralyzing Silkworm Larvae: Bacterial (T. A. Angus), 545
- Toynbee, P. A.: Awarded a New Zealand National Research Fellowship, 193
- Trade Union Education (Report from a Working Party set up by the Workers' Educational Association), 706
- Trade Union Organization: Trends in (P. C. Roberts), 383
- Trial Award and Medal of the Linnæan Society of London awarded to Prof Irene Manton, 571, 1025
- Training of Biologists (Institute of Biology Discussion on), 291, 897
- Trans-Atlantic Profile of Total Magnetic Intensity and Topography, from Dakar to Barbados (B. C. Heezen, M. Ewing and E. T. Miller), 528
- Trans-European Television, 1123
- Transfer of Internal Energy in Molecular Collisions of Flexible Hydrocarbons (W. D. McGrath and Prof. A. R. Ubbelohde), 990
- Transformation in Tetra-acyl-D-ribofuranose: A Solid State (Dr. A. L. Patterson and Barbara P. Groves), 398
- Transformation of White to Grey Tin: Effect of Germanium on the (R. R. Rogers and J. F. Fyfe), 290
- Transformers Wound without Wire (Bell Telephone Laboratories), 152
- Transformers: Irradiation of (C. D. Florida, F. R. Holt and J. H. Stephen), 397
- Transition Point between β - and γ -Sulphur: Possible Existence of a (R. S. Bradley, Dr. N. H. Harkness and M. Thackeray), 400, erratum, 476
- Translation at a Scientific Meeting: Simultaneous, 1213
- Transmission of Electrons and Holes across a Twin Boundary in Germanium (Dr. E. Büllig and M. S. Ridout), 496
- Transmission Method: Application of, to Acetyryl-Light Scattering by Very Large Molecules (M. L. R. Harkness and A. Wassermann), 147
- Tranter, Prof. C. J.: Appointed Bathurst professor of mathematical physics in the Royal Military College of Science, Shrivenham, 241; work of, 241
- Tranter, T. C.: Crystal Structure of Glycyl-L-Alanine Hydrobromide, 221
- Travelling Fellowships (Institution of Mining and Metallurgy), 153
- Travelling Fellowships in Medicine: Eli Lilly (Medical Research Council), 245
- Travelling Scholar and International Understanding, 1
- Travelling Scholar in Europe—British Council Activities, 528
- Traylor, Dr. L. R. G.: Methods of Presenting Rheological Results and their Relations, 156
- Friction in relation to Rheological Properties, 899
- Trembley, Abraham, of Geneva—Scientist and Philosopher, 1710-1784 (Dr. John R. Baker), *review* by Prof. Charles Singer, 597
- Tremlett, R. K.: Appointed agricultural officer, Zanzibar, 896
- Treponeumosis (Non-venereal): Venereal Diseases and (World Health Organization International Award for work on), 1171
- Tribe, Dr. D. E., and others: Response of Cobalt-deficient Sheep to Oral Administration of Penicillin, 728

- Triphysis Laboratory of the Commonwealth Scientific and Industrial Research Organization, Australia: New (Dr. W. Bost), 969
- Trichomonas vaginalis: A Variable Morphological Character of (Dr. Joseph G. Fenberg), 456
- Tridac (Freshwater): A New Species of, belonging to the Genus Polycelis (Dr. Eva Hansen-Møller, Mrs. Yngve Møller and Dr. T. B. Reynolds), 354
- Trigloin on Dismal: Etch (Dr. J. P. H. Custers and H. R. Simpson), 738
- Trigloin, Prof. V. M., and others: Enzymic Iodination of Milk Proteins, 905
- Trinidad: Cacao Research in—Report for 1945-51 (Dr. E. E. Cheesman), 115
- Trinity College, Cambridge: Research Studentships and Commonwealth Exhibitions, 195
- Tropical Development: Africa, a Study in (Prof. L. Dudley Stamp), review by R. W. Steel, 369
- Tropical Hygiene for Laymen: Course in (Ross Institute of Tropical Hygiene), 476
- Trotman-Dickenson, Dr. A. F.: Unimolecular Gas Reactions, 809
- Trotter, I. F.: Structure of Procaine, 58
- Trotter, I. F., and others: Alpha- and Beta-Forms of Poly-L-Alanine, 27
- Trough for Paper Chromatography consisting of Segments (Dr. Ch. Wandler), 267
- Trout: Spawning Site of (T. A. Stuart), 354
- Trowee, F. W.: Fast Chemical Reactions, 1163
- Trueman, Sir Arthur: Degree of LL.D. honors cause of the University of Leeds conferred on, 1025
- Honorary degree of LL.D. of the University of Glasgow conferred on, 1217
- Truesdale, G. A., and Downing, A. L.: Solubility of Oxygen in Water, 1236
- Trumble, H. C., and others: Legumes in Agriculture (Report of the United Nations Food and Agriculture Organization), 243
- Trump, E. C.: Appointed field zoologist, Veterinary Department, Kenya, 760
- Trunk Implantation: Application of a Systemic Insecticide by, to control a Mealybug Vector of the Cacao Swollen Shoot Virus (Dr. A. D. Hanna and J. Nicol), 730
- Truss: Influence of Position of, on Melococcy in Tomato (Dr. Gordon Haskell), 311
- Trypanosoma cruzi: A Liquid Medium for the Cultivation of (Nathan Cifer and Dr. Nathan Grossowicz), 1100
- Trypetin and Thylacocystes: Effects of, upon the Nemastocytes of the Sea Anemone (T. M. Taniguchi and Taneiro Wada), 171
- Tschische, Prof. R.: Recent Advances in the Chemistry and Biology of the Psaridines, 1176
- Tsescie Hy and Trypanosomiasis Research Committee: Report of the, 374
- Tsukada, Yasuzo, and Takagaki, Genkichi: Ammonia-formation Systems in Brain Tissue, 1138
- Tuberculosis: Dorothy Temple Cross Research Fellowships in (Medical Research Council), 245
- Tuberculosis (Experimental): Effect of, on the Distribution of Alkaline Phosphatase in the Adrenal Cortex of the Guinea Pig (Dr. Amlia B. Kar), 210
- Tubes: Diffusion and Mass Transport in (Sir Geoffrey Taylor), 244
- Tucker, R. G.: A Method for the Determination of Penicillins, 85
- Awarded a Junior Bert Memorial Fellowship for Medical Research, 981
- Tuition Scholarship (Colorado School of Mines), 526
- Tumour Cells (Mouse Ascaris): In vitro Cultivation of, for Virus-Host Cell Studies (Dr. Benjamin V. Siegel), 584
- Tumour-Inhibitory Substance: Azoxerone, a New—Studies with Crocker Mouse Sarcoma 180 (Dr. C. Chester Stock, H. Chrusone Reddy, Sonja M. Buckley, Donald A. Clarke and C. P. Rhoads), 71
- Antibiotic Studies of Azoxerone (John Ehrlich, Lucia E. Anderson, George L. Coffey, Arthur B. Hilegas, Mildred P. Knudsen, Harold J. Koepsell, Dorothy L. Kohberger and Julian E. Oynes), 72
- Isolation and Characterization of Azoxerone (Quentin R. Burtz, Carole C. Elder, Roger P. Frohardt, Salvatore A. Frazzini, Theodore H. Haskell, Doris W. Johannessen and Albert Ryder), 72
- Tumours (Mammary): Inhibition of, during Lactation Induced in Virgin Mice (Thomas A. Deane, Lowell L. Sparks, Prof. William R. Lyons, Prof. Choh Hao Li, R. David Cole and Teiruo Hayashida), 1035
- Tumours (Ovarian): Induction of, with 9-10-Dimethyl-1-2-Benzanthracene (James Marchant, Prof. J. W. Orr and Prof. D. L. Woodhouse), 307
- Tunicates: Chromosome Counts in, and a Modified Method for making Permanent Squash Preparations (L. O. Zwillenberg and H. H. L. Zwillenberg), 876
- Tupper, R., and others: Estimation of Zinc in Biological Specimens—Determination of Zinc-65, 348
- Tupper, R., and Watts, R. W. E.: Estimation of Zinc in Biological Specimens—Separation of Radioactive Zinc from Cyclotron-irradiated Copper, 349
- Turbulence (Homogeneous): The Theory of (Dr. G. K. Batchelor), review by Prof. M. J. Lighthill, 746
- Turbulent Motion of Fluids, review by Prof. M. J. Lighthill, 746
- Turkey: Scientific and Technical Documentation in (Mrs. Lucia Maholy), 811
- Turkish National Institute of Bibliography: Bibliography of Articles appearing in Turkish Periodicals, 195
- Turkish Periodicals: Bibliography of Articles appearing in (Turkish National Institute of Bibliography), 195

- University and the Nation: Physics in the (Prof. R. Whiddington), 1073
- University of Aberdeen: Appointment of Dr. A. B. Stewart to the Scratch-Fordyce chair of agriculture, 241
- Appointment of Dr. D. J. Finney to the new post of reader in statistics and director of the Agricultural Research Council's Unit of Statistics, 569
- Retirement of Prof. John Crulldashank from the chair of bacteriology, 710
- Appointment of Dr. A. Macdonald to the chair of bacteriology, 710
- University of Birmingham: Grant of £2,000 a year for seven years from the Dunlop Rubber Co., mainly to establish a Dunlop Fellowship for research work on the chemistry of high polymers, 195
- Appointment of Dr. J. Hardwicke as lecturer in experimental pathology, 333
- Appointment of Dr. J. B. Fines and Dr. W. F. R. Pover as lecturers in pharmacology, 338
- Title of University Research Fellow in Chemistry conferred on Nadim A. Ghannam, Dr. Herbert A. Laitinen, Dr. W. G. P. Robertson, Dr. W. Brock Neely and G. Vaughan, 338
- Resignation of Dr. B. A. Petrich as lecturer in pharmacology, 338
- Resignation of G. D. Mitchell as lecturer in sociology, 338
- Establishment by the Gas Council of three Scholarships in the Department of Chemical Engineering, 338
- Expedition to the Sahara Desert organized by Dr. E. B. Edney and Dr. J. Kolbozewski, 338
- Expedition to west Spitzbergen organized by P. A. Garnett in conjunction with the University College of the South-West, Exeter, 338
- Huxley Lecture (Dr. D. M. S. Watson), 338
- Appointment of N. G. T. Ludlow as lecturer in mining, 1025
- Appointment of Dr. P. D. Whittaker to the D.S.I.R. research staff in physics, 1025
- Title of University Research Fellow conferred on Harald Klepp, Prof. H. L. Saba and Dr. Bernard Shaw, 1025
- Resignation of Dr. Elsie A. G. Knowles as lecturer in industrial statistics, 1025
- Resignation of A. R. Harding as research fellow in metallurgy, 1025
- Resignation of F. Aughtie as research fellow in physics, 1025
- Resignation of G. Marchant as lecturer in geology, 1025
- Discussion on Recent Developments in Great Britain in the Study of the Permanent Magnetization of Rocks, 1114
- Title of reader in analytical chemistry conferred on Dr. R. Belcher, 1217
- Title of University Research Fellow conferred on Prof. D. L. Anderson and W. D. Seymour, 1217
- Appointment of Dr. J. D. Eshelby as lecturer in physical metallurgy, 1217
- Appointment of Dr. A. B. Foster as I.C.I. Fellow in the Department of Chemistry, 1217
- Appointment of F. Edmondson as Leverhulme Fellow in the Department of Engineering Production, 1217
- University of Bristol: Retirement of Prof. W. E. Garner from the Leverhulme chair of physical and inorganic chemistry, 523
- Appointment of Prof. D. H. Everett to the Leverhulme chair of physical and inorganic chemistry, 523
- Appointment of Prof. M. H. L. Pryce as Henry Overton Wills professor of physics, 710
- Appointment of Dr. F. C. Frank to a third chair of physics, 1072
- University of Bristol (H. H. Wills Physical Laboratory), and others: Conference on Defects in Crystalline Solids, 153
- University of Cambridge: Election of Prof. H. C. Longuet-Higgins to the John Humphrey Plummer chair of theoretical chemistry, 153
- Summer School in Programme Design for Automatic Digital Computing Machines to be held in the Mathematical Laboratory, 981
- Honorary degree of Sc.D. conferred on Prof. P. M. S. Blackett and Sir Charles Dods, 1171
- Honorary degree of Litt.D. conferred on Miss Gertrude Eaton-Thompson, 1171
- University of Durham: Appointment of Prof. W. P. K. Wynne-Jones as professor of chemistry and head of the Chemistry Department, King's College, Newcastle-upon-Tyne, 426
- Retirement of Prof. G. R. Clemo from the chair of organic chemistry at King's College, Newcastle-upon-Tyne, 426
- Appointment of Prof. F. S. Spring to the chair of organic chemistry at King's College, Newcastle-upon-Tyne, 426
- Appointment of Dr. J. M. Coulson as professor of chemical engineering at King's College, Newcastle-upon-Tyne, 1023
- University of Edinburgh: Foundation of a chair of chemical technology and the Institution of new degree of bachelor of technological science, 524
- University of Glasgow: Retirement of Prof. T. M. MacRobert from the chair of mathematics, 615
- Appointment of Prof. R. A. Rankin to the chair of mathematics, 615
- New Buildings for the, 1119
- Conferment of honorary degrees of LL.D., 1217
- University of Hull: Charter constituting and founding the, 978
- University of Leeds: Appointment of Dr. J. Sikorski as lecturer in textile physics, 195
- Gift of £700 from the Anglo-Iranian Oil Co., Ltd. to the Department of Physical Chemistry for research, 570
- Gift of 5,000 dollars from the Rockefeller Foundation of New York for research in radiation chemistry, 570
- Gift of £250 from the Anglo-Iranian Co., Ltd. to the Department of Textile Industries for research, 570
- Gift of £500 from the Cement and Concrete Association to the Department of Civil Engineering for scholarships, 570
- Gift of £200 a year for seven years from Wm. Alney and Son (Leeds), Ltd., for scholarships in concrete technology, 570
- Gift of £5,000 from the British Silk Dyeing Co., Ltd., Alexandria, Scotland, to the Department of Colour Chemistry and Dyeing for research, 570
- Jubilee of the (Prof. D. G. Christopherson), 748
- Degree of LL.D. honoris causa conferred on Sir Arthur Trueman, 1025
- Appointment of Dr. Francis O. Flint as lecturer in the Department of Leather Industries, 1025
- Gift of £1,000 from the Shell Petroleum Co., Ltd. to the Department of Coal Gas and Fuel Industries, 1025
- Gift of a specially ruled diffraction grating from Prof. M. Siegbahn to the Department of Physics, 1025
- Gift of £2,000 a year for seven years from Brotherton and Co., Ltd., for lectureships and fellowships in chemistry and chemical engineering, 1025
- Appointment of Dr. C. S. Wherwell to the chair of textile technology, 1072
- Appointment of Dr. S. E. Toulmin to the chair of philosophy, 1123
- Appointment of J. B. Border as senior agricultural economist in the Department of Agriculture, 1217
- Appointment of Prof. B. E. Douglas and Prof. H. Taube as Brotherton research lecturers in physical chemistry, 1217
- Appointment of E. W. Bennett as lecturer in the Department of Civil Engineering, 1217
- Gift of £700 from Newton Chambers and Co., Ltd., to the Department of Bacteriology for research, 1217
- University of Liverpool: Retirement of Prof. J. Proudman from the chair of oceanography, 1022
- Appointment of K. F. Bowden to the chair of oceanography, 1023
- Grant of 1,500 dollars from the Rockefeller Foundation of New York, 1080
- Symposium on the Comparative Endocrinology of Vertebrates, 1217
- University of London: Appointment of Prof. A. D. Young to the University chair of aeronautical engineering at Queen Mary College, 64
- Title of professor of veterinary bacteriology in the University conferred on Dr. Reginald Lovell, 64
- Title of professor in experimental biochemistry in the University conferred on Dr. C. J. O. R. Morris, 64
- Title of reader in anthropology in the University conferred on Dr. J. A. Barnes, 64
- Title of reader in Egyptian archaeology in the University conferred on A. J. Arkell, 64
- Title of reader in micropaleontology in the University conferred on Dr. Tom Burnard, 64
- Title of reader in geography in the University conferred on Dr. W. R. Mead, 64
- Title of reader in philosophy in the University conferred on Dr. Ruth L. Saw, 64
- Title of reader in logic and scientific method in the University conferred on Dr. J. O. Wisdom, 64
- Appointment of H. Bondi to the chair of applied mathematics at King's College, 191
- Appointment of Prof. John Yudkin to the University chair of nutrition at Queen Elizabeth College, 292
- Title of professor of civil engineering in the University conferred on J. W. H. King, 292
- Title of reader in photogrammetry in the University conferred on Dr. E. A. Makhn, 292
- Mineral Dressing at the Royal School of Mines (E. J. Pryor), 565
- Appointment of Dr. A. R. Ubbelohde to the University chair of thermodynamics in the Imperial College of Science and Technology, 571, 710
- Title of professor of cytogenetics in the University conferred on Prof. P. C. Koller, 615
- Report of the Imperial College of Science and Technology for the Year 1952-53, 616
- Appointment of Dr. D. N. Baron to the University readership in chemical pathology at the Royal Free Hospital School of Medicine, 619
- Appointment of Dr. Eleanor J. Zalms to the University readership in pharmacology at the Royal Free Hospital School of Medicine, 619
- Appointment of Dr. P. Du Val to the University readership in geometry at University College, 619
- Title of reader in mathematics in the University conferred on T. V. Davies, 619
- Preparation of a complete list of anyone associated with University College, 619
- Appointment of Prof. T. H. Marshall to the Martin White chair of sociology in the London School of Economics and Political Science, 667
- Title of reader in education in the University conferred on A. C. P. Beales, 667
- Research Activities at the Royal College of Science (Imperial College of Science and Technology) during 1950, 1951 and 1952, 758

- Appointment of Dr. F. E. Camps to the part-time University readership in forensic medicine at London Hospital Medical College, 807
- Appointment of Dr. G. E. Francis to the University readership in biochemistry at St. Bartholomew's Hospital Medical College, 837
- Discussion in the Department of Chemistry of University College on Unimolecular Gas Reactions, 809
- Appointment of Dr. D. B. Spalding to the University readership in applied heat at the Imperial College of Science and Technology, 896
- Title of professor of chemical pathology in the University conferred on Dr. F. T. G. Prunty, 981
- Title of reader in chemical biophysics in the University conferred on Dr. R. A. Kekwick, 981
- Grant of 8,000 dollars from the Rockefeller Foundation of New York for research in electrophysiology at King's College, 1080
- Grant of 1,325 dollars from the Rockefeller Foundation of New York to enable Prof. George C. Allen of University College to renew his acquaintance with economic conditions and scholarly work in Japan and the United States, 1080
- Grant of 24,000 dollars from the Rockefeller Foundation of New York for the purchase of an electron microscope to be used in King's College for research in biophysics, 1080
- Appointment of Dr. C. B. B. Downman to the University readership in physiology at the Royal Free Hospital School of Medicine, 1171
- University of London Department of Extra-Mural Studies (Atomic Scientists' Association and the): Public Lectures on Atomic Energy, 386, 477, 573, 621, 668, 859
- University of London Institute of Education: Diploma in Health Education, 664
- University of Minnesota: Histochemistry and Cytochemistry in the, 109
- University of Nottingham: Appointment of Dr. D. D. Eley to the chair of physical chemistry, 62
- Gift of £100,000 from the Boots Pure Drug Co., Ltd., for endowment of two new professorial chairs to be known as the Lord Trent chair of pharmaceutical chemistry and the Lady Trent chair of chemical engineering, 524
- Election of Dr. F. L. Milthorpe to the newly established chair of agricultural botany in the Department of Agricultural Sciences in the School of Agriculture, 756
- Appointment of Dr. J. W. Cuthbertson to the Cripps chair of metallurgy, 1023
- Resignation of Prof. H. Cotton from the chair of electrical engineering, 1122
- Appointment of Dr. J. E. Purton to the chair of electrical engineering, 1122
- University of Oxford: Twenty-eighth Annual Report, 1951-52, of the Imperial Forestry Institute, 250
- Pitt Rivers Museum Occasional Papers on Technology, 6, Stone-worker's Progress: A Study of Stone Implements in the Pitt Rivers Museum (Sir Francis H. S. Knowles), review by M. C. B., 327
- Readership in metallurgy in memory of Dr. George Kelley to be established by the Pressed Steel Co., Ltd., 1123
- University of Pennsylvania (United States Office of Naval Research and the): Symposium on the Origins of Drug Resistance, etc., 292
- University of Reading: Retirement of Prof. W. B. Brierton from the chair of agricultural botany, 894
- Appointment of Dr. D. W. Goodall to the chair of agricultural botany, 894
- Retirement of Prof. E. H. Neville from the chair of mathematics, 1168
- Appointment of Dr. R. Rado to the chair of mathematics, 1169
- University of Sheffield: Fellowship for research in ferrous metallurgy endowed by the United Steel Companies, Ltd., 476
- Appointment of Dr. A. R. Entwistle as the first holder of the United Steel Companies Fellowship for research in ferrous metallurgy, 476
- Retirement of Prof. E. J. Wayne as professor of pharmacology and therapeutics, 569
- Appointment of Dr. G. M. Wilson as professor of pharmacology and therapeutics, 569
- Title of reader in plant physiology conferred on Dr. J. G. Borwell, 619
- Title of reader in vertebrate zoology conferred on Dr. E. T. B. Francis, 619
- New Chemical Laboratories opened by the Earl of Scarborough, 623
- Honorary degrees conferred on Sir Cyril Hinshelwood, Prof. C. K. Ingold and T. A. McKenna, 623
- Appointment of Dr. D. H. Collins to the chair of pathology, 663
- Bequests under the wills of the late Sir George Franklin and Miss Daisy Franklin to be used to endow the Sir George Franklin chair of medicine, 667
- First award of the J. H. Andrew Research Fellowship in Metallurgy made to R. G. Ward, 981
- Establishment of a Department of Geotectonics, 1212
- University of Southampton: Retirement of Miss F. C. Miller as head of the Department of Geography, 757
- Appointment of F. J. Monkhouse as professor of geography, 757
- Fewley Foundation Lectures (Sir Harold Hartley), 1126
- University of Sydney: Appointment of Dr. Harry Meisel as head of the School of Physics, 241
- Appointment of Dr. E. P. George to look after the experimental programme in the School of Physics, 241
- Appointment of Dr. A. J. Herz, Dr. D. D. Miller and Dr. H. D. Rathgeber as members of the experimental team, 241
- Appointment of Dr. J. Blatt, Dr. S. T. Ma and Dr. M. R. Schafroth as members of the theoretical team, 241
- University of the Witwatersrand: Retirement of Dr. Humphrey R. Rausas as vice-chancellor and principal, 17
- Appointment of Prof. W. G. Sutton as principal, 17
- University College, Cardiff: Retirement of Prof. R. T. Dunbar from the chair of physics, 568
- Appointment of Prof. A. J. C. Wilson to the chair of physics, 568
- Appointment of Prof. Emrys Williams to the new chair of electrical engineering, 852
- University College, Exeter: Appointment of Prof. J. W. Cook as principal, 62
- University College, London: Title of reader in Egyptian archaeology in the University of London conferred on A. J. Arkell, 64
- Title of reader in micropaleontology in the University of London conferred on Dr. Tom Barnard, 64
- Title of reader in geography in the University of London conferred on Dr. W. R. Mead, 64
- Title of reader in photogrammetry in the University of London conferred on Dr. E. A. Miskin, 292
- Appointment of Dr. P. Du Val to the University of London readership in geometry, 619
- Preparation of a complete list of anyone associated with the College, 619
- Discussion in the Department of Chemistry on Unimolecular Gas Reactions, 809
- Grant of 1,525 dollars from the Rockefeller Foundation of New York to enable Prof. George C. Allen to renew his acquaintance with economic conditions and scholarly work in Japan and the United States, 1080
- University College, London (Statistical Department): Elementary Statistical Exercises, Part I, review, 325
- University College of North Staffordshire: New Physics Laboratories (Prof. F. A. Vick), 154
- To confer degrees for the first time, 710
- Appointment of A. G. N. Flew as professor of philosophy, 1171
- Appointment of Dr. D. G. Holloway as assistant lecturer in physics, 1171
- University College of North Wales: Retirement of Prof. E. A. Owen from the chair of physics, 756
- Appointment of Dr. E. R. Andrew to the chair of physics, 756
- University College of the South-West, Exeter (Garrett, P. A., in conjunction with the): Organization of an expedition to West Spitzbergen, 338
- University College, Swansea: Appointment of Dr. B. G. Neal to the first chair of civil engineering, 663
- Appointment of Dr. W. G. V. Balchin to the newly established chair of geography, 756
- Retirement of Prof. Florence Mockridge from the chair of biology, 804
- Appointment of Prof. H. E. Street to the chair of biology, 804
- University College of the West Indies: Department of Zoology (Prof. N. Milford), 858
- University Education in Central Africa, 1007
- University Entrance Examinations: European Convention on the Equivalence of, 711
- University Interchange between the United Kingdom and other European Countries, 1948-53 (British Council Report on), 528
- University Physics in Great Britain, 1073
- University Students: Selection of, 91, 1055
- University Teachers: Chinese, under Sovietization (Dr. F. C. Jones), 713
- University Visitors to Great Britain, 526
- Unpublished Mathematical Tables. Depository of (Royal Society), 1221
- Unsuccessful Attempt to demonstrate a Paralytic Factor in Serum of Myxema Gravis Patients (Dr. W. Lambers and Dr. v. D. Most van Spijk), 1192
- Unusual Virus Disease of a Dipterous Larva (Dr. Kenneth M. Smith and N. Xarou), 866
- Uptake of Radioactive Carbon and Phosphorus by Paratized Leaves (Dr. M. Shaw, Dr. Stewart A. Brown and Dr. D. Rudd Jones), 768
- Uptake of Sucrose by Leaf Tissues: Effect of Mercury Vapour on the Active (G. A. Pennell and Dr. P. E. Weatherley), 1096
- Urey, Prof. Harold C.: The Planets, their Origin and Development, review by Dr. R. Stonley, 1154
- Urinary Extracts: Elimination of the Fluorescence of Estrogens In, by Hydrogen Peroxide (C. Heughebaert), 1043
- Urine: Paper Chromatography for the Separation of Neutral 17-Ketosteroids In (Sheila McDonough), 645
- Urine (Human): Gonadotrophins In (Joyce D. Ingram, W. R. Butt and Dr. A. C. Crooke), 85
- Urine (Normal): Identity of Auxin in (O. P. Wieland, R. S. de Ropp and Mrs. J. Ayres), 776
- Uterus (Pregnant Rabbit): Bicarbonate Content of the Blastocyst Fluid and Carbonic Anhydrase In the (Dr. C. Lutwak-Mann and Dr. H. Lasser), 268
- Utilization as Food of Fish and Agricultural Products and their By-products: New Developments in the (Aberdeen Section and the Food and Agriculture Groups of the Society of Chemical Industry and the Scottish Branch of the Institute of Biology Conference on), 339
- Utilization of Sulphate labelled with Sulphur-35: Influence of Vitamin C on the, in the Synthesis of Chondroitin Sulphate of the Costal Cartilage of the Guinea Pig (Dr. K. K. Reddi and Ana Norstrom), 1232
- Utilization of Topically Applied Methionine by the Guinea Pig (Dr. L. J. Edwards), 1042
- Uvarov, Dr. B. F.: Acoustics of Orthoptera, 1219
- VACCINATION** against Haemorrhagic Septicaemia of Bovines (Dr. R. V. S. Bain), 584
- Vacua: High (Committee on Vacuum Techniques Symposium on), 667, 855
- Vacuum Techniques: Development and Research in, 982
- Vacuum Techniques: Committee on Symposium on High Vacuum, 667, 855
- Vacuum Ultra-Violet: Measurement of Spark Spectrum Intensities in the, with a Photomultiplier sensitized to Fluorescence (V. W. Maslin, M. R. Mahony and Dr. S. E. Williams), 76
- Vagina (Rabbit): Absorption of Phosphorus-32 from the, under various Hormonal Conditions (Dr. Lars Ph. Bengtsson), 954
- Valency in Organic Chemistry: Electronic Theory of, review by Dr. J. C. Speakman, 917
- Vale, Dr. Joan M.: Awarded a National Research Council of Canada Fellowship for Medical Research, 1216
- Valentine, Prof. D. H.: Plant Form and Function, review, 700
- Vallé, Prof. Giorgio: Obituary by Dr. A. von Engel, 472
- Valone: Insecticidal Synergism with (P. S. Hewlett), 132
- Valone: Structure of Cell Wall of (Prof. R. D. Preston and Prof. W. T. Aubrey), 203, (Prof. R. C. Steward and Prof. K. Mühlethaler), 204
- Van der Byl, Morkel, W. F.: Appointed agricultural officer, Northern Rhodesia, 194
- van Kesterik, V. M., and Huis in't Veld, Dr. L. G.: Metabolism of Glycyrhizic Acid in Human Subjects, 733
- Van Nostrand Chemical's Dictionary (edited by Prof. Jürgen M. Honig, Dr. Morris B. Jacobs, Prof. S. Z. Levitt, William R. Minneth and Dr. George Murphy), review by R. Brightman, 1010
- Vanadate Glasses (E. P. Denton, H. Rawson and J. E. Stanworth), 1030
- Variation (Annual): Very Long Sequences of Geomagnetic Activity and its (B. N. Bhargava and Ali H. Nevil), 498
- Variation of Hardness of Metals with Grain Size (Dr. E. O. Hall), 948

- Variation within Inbred Strains of Mice (Dr. H. Grüneberg), 674
- Variations: Calculus of, by Parallel Displacement (Prof. W. S. Kimball), *review* by Prof. H. T. H. Piaggio, 1156
- Variations of Eclipsing Variable Stars. Determination of the (R. Stazniecek), 110
- Varieties in relation to Crop Production (National Institute of Agricultural Botany Second Crop Conference), 198
- Vascular Plants common to the Arctic and the British Isles (Dr. Nicholas Polunin), 816
- Vaughan, G.: Title of University Research Fellow in chemistry in the University of Birmingham conferred on, 338
- Vaughan, N. B. (edited by) *Journal of the Institute of Metals*, Vol. 78 (1950-51), Vol. 79 (1951), *review* by Dr. W. Hume-Rothery, 1158
- Metallurgical Abstracts (General and Non-Ferrous), Vol. 18, 1950-51 (New Series), *review* by Dr. W. Hume-Rothery, 1205
- Vecchia, O.: General Problems in Exploration Geophysics, 247
- Vegetation Classification of (D. W. Goodell), 384
- Velocity Distribution of Sporadic Meteors (Mary Almond, J. G. Davies and Prof. A. C. B. Lovell), 4, Extension to Magnitude +8 and Final Conclusions, 861
- Venables, Dr. P. F. R.: Technical Education, 197
- Elected president of the Manchester Literary and Philosophical Society, 1025
- Veneral Diseases and Non-venereal Treponematoses (World Health Organization International Award for work on), 1171
- Venom (Egyptian Scorpion and Cobra): Influence of, on Mammalian Erythrocytes *in vitro* (Dr. A. H. Mohammed, H. Rohayem and O. Zaky), 170
- Ventura Species: Significance of the Ratio between the Water-soluble Aromatic and Nitrogen Constituents of Apple and Pear in the Host-Parasite Relationships of (D. S. Kurkham), 690
- Verband Deutscher Physikalischer Gesellschaften, 427
- Vercouture, M.: Engineering Dimensional Metrology, 293
- Verdoorn, Dr. F.: Botanical Histology, 482
- Verma, Mukh Raj, and Paul, Sukh Deo: Volumetric Method for the Determination of Zirconium, 1237
- Vermuyden and the Fans (L. E. Harris), *review* by Prof. H. C. Darby, 913
- Vernalization: Anatomy of Roots and Shoots of *Brassica campestris* L. in relation to (S. C. Chakravarti), 407
- Vernon (H. M.): Prize of the National Institute of Industrial Psychology awarded to Dr. N. H. Mackworth, 292
- Verssen (Nickel): Effect of, on Oak Plants (William M. Crooke), 403
- Vertebrae of Spitzbergen: The Devonian and Devonian, Vol. 9, Parts A and B (Gustav Wülfing), 713
- Vertebrates: The Comparative Endocrinology of (Symposium at the University of Liverpool) 1217
- Vertebrates without Erythrocytes and Blood Pigment (Prof. Johan T. Ruud), 848
- Very-High-Frequency Broadcasting in Great Britain, 297
- Vesine, E. H.: Elected a member of the National Academy of Sciences, Washington, 1173
- Veterinaria Italiana, 805
- Veterinary College, Royal: Title of professor of veterinary bacteriology in the University of London conferred on Dr. Reginald Lovell, 64
- Appointment of Prof. J. McCune as acting principal, 1171
- Veterinary Department, Kenya: Appointment of W. P. Langridge as field zoologist, 112
- Appointment of E. C. Trump as field zoologist, 763
- Veterinary Department, Nigeria: Appointment of A. R. Mahood as entomologist, 760
- Vibrations as a Cause of Disintegration in Liquid Sheets (R. P. Fraser, N. Dombrowski and P. Eisenklam), 495
- Vida faba: Delay of Chromosome Rejoining in, induced by Irradiation (Sheldon Wolf), 501
- Vick, Prof. F. A.: University College of North Staffordshire—New Physics Laboratories, 154
- Vickers, G. C.: Appointed veterinary officer, Jamaica, 194
- Victoria (Western): Geological Evidence in, relative to the Antiquity of the Australian Aborigines (E. D. Gill), 1124
- Vignaud, Prof. V. du, and others: Synthesis of Oxytocin, 1215
- Villars, Donald Stadler: Statistical Design and Analysis of Experiments for Development Research, *review* by M. R. Sampford, 327
- 'Vipagel', a New Modelling Medium (Dr. H. F. Steadman), 476
- Violet Pigment from the Mediterranean Medium *Rhizostoma pulmo* (Dr. A. Christmann), 875
- Virgin Mice: Inhibition of Mammary Tumours during Lactation Induced in (Thomas A. Deane, Lowell L. Sparks, Prof. William R. Lyons, Prof. Choh Hao Li, R. David Cole and Tetsuo Hayashida), 1035
- Vird Valley, Peru: Prehistoric Settlement Patterns in the (Gordon R. Welley), 625
- 'Virulence of Autotrophic Mutants of *Erwinia arorae* (Dr. E. D. Garber and Adeline J. Hackett), 88
- Virulence in Influenza Viruses. Genetics of (Sir Macfarlane Burnet and Patricia E. Lind), 627
- Virus (Cacao Swollen Shoot). Application of a Systemic Insecticide by Trunk Implantation to control a Mealybug Vector of the (Dr. A. D. Hanna and J. Nicol), 730
- 'Virus (Incomplete Influenza): Artificial Production of (Dr. S. Fazekas de St. Groth and Doris M. Graham), 637
- 'Virus (Influenza A): Lipid Content of 'Standard' and 'Incomplete' (Marjanne Uhler and Prof. Sven Gard), 1041
- 'Virus (Rift Valley Fever). Different-sized Infective Particles of (W. du Toit, Naudé, T. Madsen and Dr. A. Tolson), 1051
- 'Virus to Aphids: Ultra-Violet Irradiation of Tobacco Infected with Potato Virus Y and the Availability of (Dr. H. R. E. Bradley), 350
- 'Virus Complex: Canine Distemper (Dr. N. M. Larm), 174
- 'Virus Disease of a Dipicous Larva. An Unusual (Dr. Kenneth M. Smith and N. Xaroe), 866
- 'Virus Latent in Carnation and Potato Plants (Dr. B. Kaseanu), 1097
- 'Virus Particles: Internal Structure in (Councilman Morgan, Solon A. Ellison, Harry M. Rose and Dr. Dan H. Moore), 208
- 'Virus Research: Advances in (edited by Kenneth M. Smith and Max A. Lauffer), Vol. 1, *review* by P. C. Bawden, 324

AN 'UNBACKED' MERCURY VAPOUR PUMP

PERFORMANCE	
Ult. VACUUM	10 ⁻⁴ mm Hg
SPEED	
Unbaffled	70-80 Lit./Sec.
Baffled	30-40 Lit./Sec.
Max. Backing Pressure	30-35 mm. Hg
Heating Loading	850 watts

—well, not exactly, but the 'SPEEDIVAC' 2M4 can in many cases be completely isolated from the backing pump for long periods, thus providing an absolutely quiet and vibrationless system.

OTHER VALUABLE ADVANTAGES INCLUDE:

- ★ Outstanding high vacuum performances maintained against backing pressures as high as 30 mm. Hg with moderate heater input.
- ★ In an emergency the pump can be backed by a water jet pump, a valuable advantage where corrosive vapours are involved.
- ★ Ideal for exhausting into backing capacities for gas sampling.

SCIENCE TEACHERS IN SCHOOLS

THE difficulties which many schools in Great Britain are experiencing in obtaining adequate staff for the science side are now becoming widely known. Reference has been made to this topic in these columns on many occasions during the past twelve months, and some general considerations on the implications of the shortage formed the subject of an article in *Nature* of December 19. The latest discussion on the subject was one arranged by the Federation of British Industries (see p. 196).

Just over a year ago, the actual staffing position in the schools was discussed (*Nature*, December 27, 1952), particularly as it affected the public and grammar schools. At that time there were about two hundred science posts unfilled; the close balance between supply and demand led to frequent staff changes and so there was little continuity of science teaching; the quality of both the academic and teaching ability of science teachers appeared to be lower than it was before the Second World War, and since 1950 the position was getting worse rather than better. This shortage in number and quality was ascribed to two main causes: there were not enough scientists to meet the post-war demands of industry, the Scientific Civil Service, the universities and the teaching profession; the pay of science teachers and their conditions of service compared unfavourably both with what they enjoyed before the War and with what they could now get in the other occupations open to them.

Since then, the Science Masters' Association and the Association of Women Science Teachers, and very recently the National Advisory Council for the Supply and Training of Teachers*, have issued reports on the problem. The National Advisory Council bases its conclusions on statistics obtained by the Ministry of Education and gives the administrative point of view; the teachers' associations describe the situation in the schools and reflect the front-line point of view; so the two reports are complementary.

The Council's report embraces not only public and grammar schools, but also technical and secondary modern schools and establishments of further education. It estimates that, between 1950 and 1955, 570 new science teachers will be available each year to meet an annual demand of 580 teachers. The post-war increase in birth-rate will increase the number of children in the grammar, technical and secondary modern schools from 2,000,000 in 1950 to 2,700,000 in 1960, and so the annual demand for science teachers during 1955-60 will rise to 1,020, if 1950 staffing standards are to be maintained. The Council notes that there is at present a shortage of science teachers, and that the quality of degree of the present science teachers is below its pre-war standard. It adds that the shortage will be very serious between 1955 and 1960 unless the supply of science teachers can be about doubled, by 1955. The

* Ministry of Education. Graduate Teachers of Mathematics and Science: a Report of the National Advisory Council on the Training and Supply of Teachers. Pp. iv+12. (London: H.M. Stationery Office, 1953.) 6d. net.

annual demand will fall to 380 in 1960, because the number of children in the schools will quickly decrease to its present number of 2,000,000 again. Hence, if the science teaching staff be doubled, in 1960 a number of teachers will become available for new vacancies. The Council concludes, therefore, that the serious problem is a short-term one and will be ended by about 1960, if the 1955-60 needs are met. It traces the present shortage of science teachers to three causes: the universities are not producing enough science graduates to satisfy the demands of industry, research in the universities, the Scientific Civil Service, and teaching; the pay of science teachers is inadequate; and the equipment of school laboratories and the supply of laboratory assistants are inadequate. The Council concludes by stressing that the shortage of school science teachers is not only a matter of serious concern to the schools but also to the whole nation. If it is not remedied, it will in due course decrease the number and quality of science students entering the universities, which, in turn, means that the output from the universities will fall at a time when it is essential that it should rise, to maintain and improve the standard of life in Britain. If the schools are starved of science teachers, this better supply of scientists will not be forthcoming, and the standard of life will go down at a steadily increasing rate.

The Science Masters' Association survey supports the facts in the National Advisory Council's report, and underlines the urgency of the position and the need for prompt action to remedy it. The Survey states that 115 science posts are vacant; as replies came from just over half the schools, there are probably two hundred vacant posts altogether. In eighty-four schools the teaching of one of the science subjects, physics, chemistry or biology, has been discontinued; in 1950 a report by the Incorporated Association of Headmasters noted that forty-eight schools had discontinued a subject. Both the academic and teaching ability of new science teachers is reported to be lower than it was before the War. Ten per cent of the science teachers are either non-graduates or arts graduates. Because the balance between supply and demand is so even, there is a constant movement of science staff, thus destroying the continuity of teaching in any one school. There would be many more vacant posts but for the existence of makeshift arrangements such as teachers continuing after the age of sixty-five, part-time teachers over sixty-five, part-time married women, two schools sharing the same teacher for a sixth-form science subject, and headmasters doing almost as much teaching as an assistant master. Finally, in the past ten years, 975 science teachers have left the schools either for industry or administration. The position in girls' schools is even worse than in boys' schools. Last autumn a survey by the Association of Headmistresses confirmed these facts.

The consequences of the shortage of school science teachers are now beginning to be felt. There are reports that places in university engineering schools and in hospital medical schools were unfilled at the start of the present academic year; science examiners

marking Advanced Level papers for the General Certificate of Education state that many candidates know the subject by heart without understanding it; and the quality of assistant experimental officers in the Scientific Civil Service, who are of the same standard, recruited by the Ministry of Supply is declining.

The National Advisory Council makes four main recommendations for remedying the shortage of science teachers. As the problem arises because there are not enough scientists to go round, the Council asks for a conference at the highest government level to discuss ways of securing a more equitable distribution of the available scientists among the various occupations needing them. The Council then states that pay is a major factor in the situation, but feels it cannot properly pursue this further as the pay of teachers is settled by another statutory body, the Burnham Committee. It also suggests that the output of science specialists leaving the schools for the universities could be increased with the present strength of science staff, as there are still a number of science sixth forms which could be doubled in size without overburdening the teachers. Finally, it suggests that the 'glamour' of research should be counteracted by putting the case for teaching as a satisfying career to undergraduates in the pure science departments of the universities.

The National Advisory Council is to be congratulated on its objective and restrained presentation of the situation, the seriousness of which for the whole nation it has correctly appraised. Its first remedy should be implemented without delay; it has said all it properly can about pay, but it is significant that the new salary scales which the Burnham Committee has recommended to the Minister of Education for adoption from April 1, 1954, have been rejected by the associations representing the headmasters and assistant masters of grammar schools. But is the Council right in thinking that the supply of science undergraduates can be increased with the present science teacher strength? The Science Masters' Association report shows that there are about twice as many boys in science sixth forms as there were before the War, while it is likely that the number of science teachers has only increased by ten per cent in the same time. There are many small science sixth forms in spite of the fact that the schools have made known to their pupils the great demand for scientists. Are not these small science sixth forms due partly to the fact that some of the science teachers are of such moderate ability and personality that they cannot attract any more pupils to their side of the school, and partly to the fact that, where the teacher is competent, he has already attracted all the pupils capable of doing sixth-form science? Finally, the Council has surely made a faulty diagnosis of the situation in judging it to be a short-term problem. On its own admission, it will only be a short-term problem provided the needs of 1955-60 are met, which means doubling the present supply of science teachers between 1955 and 1960. But the Council has no practical proposals for doubling the supply of science teachers by 1955 and

gives no evidence for believing that this can or will be done. If it is not done, the shortage in 1960 will be worse than it is now, because the number and quality of science graduates will have started seriously to decline; and the position will deteriorate at an increasing rate in schools, universities and industry.

It is difficult to resist the conclusion that the National Advisory Council is running away from the problem, the seriousness of which both for the schools and the nation it has so clearly stated. Why cannot the Council accept and act on the logical consequences of that statement? The shortage concerns the whole nation, because it threatens the supply of scientists and technologists essential to its well-being. The grammar schools in Britain are the main source of scientists and technologists. Surely, then, the development of secondary modern schools must take second place until the grammar schools have been made safe, so that they can satisfy the various demands for science graduates and ultimately the demand for them from the secondary modern schools themselves. At the moment, Great Britain is carrying an unprecedented load for defence in peace-time. While the resources available for education are severely limited, it is essential that the grammar schools, which are entrusted with the development of the talent of the ablest children in the country, should not be starved. They have already shown that they can carry out this task with some measure of success, and their products are in great demand for tasks of vital national importance. Their needs must be given priority in the educational system of Great Britain.

Once this decision has been taken, the way will then be clear for grappling with the problem of the present shortage in numbers and decline in quality of science teachers in the grammar schools. The solution of this problem will involve another difficult decision about the salary scales of all teachers in grammar schools. If these two issues are shirked, the Butler Act, which began by promising secondary education for all, may well in fact end by destroying the secondary education for the able children which did exist before the War in the grammar schools of Britain. The first of these two issues lies within the province of the National Advisory Council, and it should give the Minister of Education unequivocal advice on the matter.

SIR HANS SLOANE AND THE BRITISH MUSEUM

Sir Hans Sloane and the British Museum

By G. R. de Beer. (Published for the Trustees of the British Museum.) Pp. 192+11 plates. (London: Oxford University Press, 1953.) 18s. net.

IT was unfortunate that the week of the Coronation of Her Majesty coincided with, and took attention from, the centenary of another event of national importance, namely, the foundation of the British Museum. That term rightly includes not only the

vast collection at Bloomsbury but also the no less important Natural History collection at South Kensington. The British Museum was founded by Act of Parliament passed on June 7, 1753, as the direct result of the design of Sir Hans Sloane, who died a few months earlier in his tenth decade. He left his immense collections to the nation, desiring that they be used for public enjoyment and instruction and kept together "to the manifestation of the glory of God, the confutation of atheism and its consequences, the use and improvement of physics, and other arts and sciences, and the benefit of mankind". Parliament decided to combine with it two other considerable collections then available into one great national institution.

Of these collections, that of Sloane was by far the largest and most diverse. This fact and the action of the trustees named in his will, who brought the matter to the attention of Parliament, make this great physician the real founder of our national museum. Its two branches are rightly controlled by the same standing committee, thus emphasizing that any separation between the humanities and those other arts that we are accustomed to call the 'sciences' is but accidental, artificial and temporary, and that in many regions they do, in fact, overlap. This is wholly in accord with the feelings and outlook of the founder. The actual physical separation of the two types of objects was not effected for another century. It was in 1856 that the greatest of British comparative anatomists, Richard Owen (1804-92), was called as first director to South Kensington. It may well be that there is, for all institutions, an optimum size beyond which growth is harmful rather than helpful. Nevertheless, the separation of the 'sciences' from the 'arts' is a misfortune which Sloane himself foresaw and one which the present cordial relations of the two great branches of our national museum are now doing much to remedy.

Hans Sloane was born at Killyleagh, County Down, Ireland, in 1660. The name Hans—a shortened form of Johannes or John—implies no German relationship but was, it would appear, a Scottish-Irish form used at that time. He came of a fairly well-to-do family and seems never to have been in want. At nineteen years of age he came to study in London, and there he met and made friends with the illustrious naturalist, John Ray (1627-1705), and the equally illustrious chemist, Robert Boyle (1627-91). Both men influenced him deeply. After four years he left for further study in France, where he attended medical, botanical, chemical and anatomical lectures in Paris and Montpellier, but took his degree, for no very evident reason, at the obscure and now extinct University of Orange in Provence. He returned to London in 1684 and called on Thomas Sydenham (1624-89), the "English Hippocrates", with a letter from Boyle recommending him as skilled in scholarship, botany and anatomy. Sydenham read the letter, looked at the young man and said: "That is all mighty fine, but it won't do—Anatomy, Botany—Nonsense! Sir, I know an old woman in Covent Garden who understands botany better, and as for anatomy, my butcher can dissect a joint full as well; no, young man, all this is Stuff: you must go to the bedside; there alone you can learn disease".

Nevertheless, the two became fast friends. Sloane went to the bedside and became, beyond doubt, one of the most effective practitioners of his day, for,

despite the unscientific state of medicine, he was a very careful observer and had just that calm and cautious yet optimistic temperament that inspires hope and confidence in the patient. He disliked complex prescriptions, preferred to try one remedy at a time and was deeply aware of the influence of the mind on disease. In all circumstances and in any age he would have been a first-class physician.

All this is admirably told in this attractive little book by Dr. G. R. de Beer, the present director of the British Museum (Natural History). In 1687 Sloane sailed for the West Indies in the suite of the Duke of Albemarle, Governor of Jamaica. He spent some sixteen months in that island, and his report on its natural history is a classic. He returned to practise in London, occupying his spare time in accumulating, arranging and cataloguing his collections which, in course of time, became extensive. In 1695 he married and settled at 3 Bloomsbury Place, where he practised for many years. In 1712 he became physician to Queen Anne and in 1706 physician-general to the Army. In 1716 he was made a baronet, being the first medical man to receive that title. In 1719 he became president of the Royal College of Physicians, and in 1727, on the death of Newton, succeeded him as president of the Royal Society. Among his medical activities is his physiciancy of Christ's Hospital for thirty-six years, his assistance to Captain Coram (1688-1751) in instituting the Foundling Hospital in 1739, and his attempt to establish a free dispensary. He practised until he was eighty-two, when he retired to Chelsea, where he died and was buried eleven years later.

The number and variety of the collections accumulated by Sloane is truly astonishing. There were about 50,000 printed books that formed the basis of the British Museum Library, about 3,800 volumes of manuscripts, about 32,000 medals and coins, 334 volumes of dried plants which formed the basis of the British Museum Herbarium, 12,500 other specimens of plants, 5,500 insects, 1,900 quadrupeds, 1,500 fishes, 1,200 birds, and thousands of other specimens under other headings. Some idea of the variety of the collection can be gathered from a special issue of the *British Museum Quarterly* that appeared last June as a special bicentenary number. In the articles by keepers of various departments, under the general charge of the director and principal librarian, Sir Thomas Kendrick, details may be learned of the nature of the treasures in their keeping.

We cannot end without an anecdote of Sloane which may not be known to all readers of *Nature*. In 1740 the composer Handel was taking tea with Sloane, who showed him his library. Handel placed his buttered muffin on the volume in his hand. The outraged silence of Sir Hans failed to appeal him with a sense of guilt. "To be sure," Handel admitted later, "it was a careless trick, but it did no monstrous mischief; yet it put the poor old bookworm terribly out of sorts. I offered my apologies but the old miser would not have done with it. Had it been a biscuit, it would not have mattered." And Handel went on to suggest that Sloane's displeasure was due to his parsimoniousness. "But muffin and butter. And I said to myself, 'Ach, mein Gott, that is the rub! It is the butter'; which, of course, it was, but not for the reason which Handel alleged. In those days butter was not rationed—except in libraries.

CHARLES SINGH

CHEMISTRY OF STYRENE

Styrene

Its Polymers, Copolymers and Derivatives. Edited by Ray H. Boundy, Raymond F. Boyer and Sylvia M. Stoecker. (American Chemical Society Monograph Series, No. 115.) Pp. xxii+1804. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1952.) 160s. net.

THIS impressive volume is the complete guide to the chemistry of styrene, its polymers, copolymers (excluding synthetic rubber) and their derivatives. The extensive study of styrene and its polymers has had a profound effect in high-polymer chemistry as a whole, and therefore the book is of very much wider interest than its title would imply. Since it deals with every aspect of the subject from the purely academic to highly specialized technology, it has to be a composite work from a number of pens. Its editors, R. H. Boundy, R. F. Boyer and S. M. Stoecker, who have themselves contributed extensively to the subject, have welded the separate articles into a coherent whole so effectively as to avoid undue overlap. With one or two exceptions the authors are members of the Dow Chemical Co., which pioneered much of the earlier work on styrene. The book, therefore, is authoritative, both on the academic and technological aspects. Besides being encyclopaedic in its contents, each contribution is a critical discussion of the topic under review. Furthermore, the wider implications of the discussion to other branches of polymer chemistry are not neglected, even though the main theme—styrene—is kept in mind. The compilation of a text of this magnitude, even with the best co-operation, occupies a considerable amount of time; but in spite of this difficulty each chapter is surprisingly up to date. In a series of appendixes to several of the chapters, more recent work up to 1951 is briefly reviewed and appropriate references quoted.

It is impossible in this brief review to do full justice to the wealth of material: it is only practicable to say something of the general arrangement and special features of the volume. The arrangement is strictly logical: the preparation and properties of styrene; polymerization methods; and the nature of the properties of the polymer, copolymers and derivatives of styrene. Although much of styrene goes into butadiene-styrene copolymers, synthetic rubber receives only a very limited treatment. Had this topic been discussed at all comprehensively, the book would have had to be doubled in size, and in any event synthetic rubber is best dealt with in a separate volume altogether.

The historical introductory chapter, when read with present-day insight, shows how much excellent knowledge there was about styrene before the intensive developments of the past fifteen years. The manufacture of styrene via ethylene and benzene is the only commercially important method, and this is dealt with in detail. Then follow particularly useful chapters thoroughly surveying the chemical and physical properties, analysis and handling of the monomer. The chapter on the polymerization of styrene is an essay in addition-polymerization in so far as the principles of the subject are concerned. Similarly, the chapter on the molecular weight of the polymer again outlines much that is of general interest in the treatment of the polymer as a high-polymer substance. No less complete are the chapters dealing with the mechanical, optical and electrical

properties of the polymer. Degradation of the polymer by all the usual agents is also treated separately. Logically, there follows a much shorter chapter concerned with the chemical modifications of the polymer. Next, the derivatives of styrene and α -methyl styrene are adequately considered, as well as the use of styrene in the production of resins of which it forms one component. The latter chapter is concerned much more with the practical affairs, and the theory is considered quite separately in a chapter on copolymerization. Since much of the work described in this volume has been done on the western side of the Atlantic, the editors have wisely introduced a chapter dealing with the German developments prior to, and during, the Second World War, which makes a very interesting comparison in the methods of approach used to solve these problems in two parts of the world.

Not content with covering the whole subject in this way, the editors arranged for a complete set of patents to form part of the book. This means that, if anything was omitted in the ordinary discussion, it is included in the considerable volume of references. A large section is devoted to the problems involved in the manipulation of the polymer as a plastic in all its variety of uses, the moulding and fabrication of sheet, and even of filaments. Although some of these processes are necessarily based on empirical knowledge, the authors of the chapters as far as possible have described fundamental principles, so that again these chapters have general interest for many other polymers with similar kinds of properties.

In short, this is a volume that anyone must possess who has to deal in any respect with styrene and its polymers. There is, too, a fund of knowledge of great interest to anyone dealing with synthetic polymers as a whole. It contains the story of an outstanding industrial achievement to a considerable extent spurred on, but not initiated, by war-time necessity.

H. W. MELVILLE

CENTRAL AMERICAN ORCHIDS

Orchids of Guatemala

By Oakes Ames and Donovan Stewart Correll. (Fieldiana: Botany. Vol. 28, No. 2.) Pp. iv+399-728. (Chicago: Chicago Natural History Museum, 1953.) 5 dollars, cloth bound; 4 dollars, paper bound.

CENTRAL AMERICA is well known as one of the richest two regions in the world for orchids, the other being New Guinea. Costa Rica, with an area about equal to that of Wales and an orchid flora consisting of about nine hundred species, is probably richer in orchids than any other comparable area; nevertheless, Guatemala, which contains more than five hundred species, may rightly lay claim to a very extensive orchid flora.

Accounts of the orchids of Costa Rica and Mexico have already been published, but in neither case in such detail nor in such an attractive manner as in the "Orchids of Guatemala". Indeed, Dr. Correll, following the death of his co-author, Prof. Ames, has produced a book which is a model of its kind, beautifully produced and printed.

Owing to the complexities of the floral structure of orchids, good illustrations are essential for their proper understanding, and these are provided on a scale seldom seen in an account of this kind. The whole book, of which this is the concluding part, contains

nearly two hundred delightful line-drawings, including illustrations of all the genera described and of many additional species. These supplement the excellent generic and specific descriptions and the workmanlike keys for the determination of the various groups. Dr. Correll, following the views of his mentor, Prof. Ames, takes a rather conservative view of species in the reviewer's opinion; but that is, of course, a matter on which no two specialists will entirely agree. Altogether, this is a book which no student of the orchids should be without and which, indeed, could well be studied with profit by workers on other groups of plants.

V. S. SUMMERHAYES

THE UNIVERSE AND ITS BEGINNING

The Creation of the Universe

By Prof. George Gamow. Pp. xii+147+12 plates. (New York: Viking Press; London: Macmillan and Co., Ltd., 1952.) 21s. net.

THE study of cosmogony occupies a peculiar position among scientific activities. From long experience it has become quite clear that, unless there are continuous and manifold checks applied to theoretical speculation, its relation to experience becomes extremely slender. The chance that pure theory, even when it has at its disposal the great volume of present-day knowledge of physics, could succeed in describing such ultimate phenomena as those concerned with the development of the universe from some elemental beginning is very small indeed. The observed data which bear on these questions are still wholly insufficient to provide a really adequate check on any hypothesis. On the other hand, it is obviously necessary in formulating any cosmological picture that it should be consistent with modern physical principles and knowledge as well as with the meagre observational data which bear directly or indirectly on the matter.

Despite the vanishingly small chance of hitting upon the actual way in which the past history of the universe has developed, the intellectual exercise involved in formulating a cosmogony consistent with the foregoing requirements is of absorbing interest. No more entertaining exponent of a scheme of this kind could be found than Prof. George Gamow, whose popularization of some of the more recondite principles of physics through the dreams of "Mr. Tompkins" are deservedly famous.

The account he gives of the development of the universe makes absorbing reading. The expert use of the most recent discoveries in nuclear physics also makes it very instructive as long as one retains due scepticism about the ultimate reality of the scheme proposed. Even the dullest of readers must be impressed by diagrams purporting to give, for example, the "Chemical changes in the universe during its first half-hour". The sheer impudence of it is breathtaking.

In the first part of the book Prof. Gamow discusses the case for a dynamic rather than static picture of the universe. He describes the evidence about the age of different parts of the universe. This evidence indicates that all parts are of about the same age—a few thousand million years—and he considers that this strongly supports the evolutionary picture.

The evolutionary picture which is proposed is based on the observational fact that the universe is

expanding. Assuming the rate of expansion to have been the same in the past, the present universe must have expanded from a state, which would have had the density of nuclear matter, about 1.7×10^6 years ago. It is this state, called the ylem, which is regarded as the primitive condition from which the universe is developed. The ylem is regarded as a nuclear gas at a temperature of many thousands of millions of degrees. In this gas protons, neutrons and electrons co-existed in a dynamical equilibrium. As the gas expanded, it cooled and nuclear synthesis began. The author claims that, by discussing the dynamics of the nuclear reactions involved, it is possible to understand the abundance distribution of the elements, which is significantly similar throughout the universe.

Having described the first hour of the embryonic universe, Prof. Gamow then considers the processes which led, through the course of a few hundred million years, to the structure of the present universe with its stars and galaxies. In the course of this he discusses many aspects of astrophysics, such as the sources of nuclear energy in the stars, which are quite well established and of great interest.

The whole book is written in a most pleasant style, and it presents a coherent argument throughout. For the professional physicist and astronomer it is well worth reading for the excellent way in which new ideas are presented and the outlook of modern physics employed. For the student or the layman it should make fascinating reading, as it is in no sense technical and has the largest possible horizon.

H. S. W. MASSEY

ELECTRON OPTICS: PURE AND APPLIED

Electron Optics

By Prof. O. Klemperer. (Cambridge Monographs on Physics.) Second edition. Pp. xiii+471. (Cambridge: At the University Press, 1953.) 50s. net.

IN describing this book one cannot help recalling the well-known lines about books written by Bacon in his "Of Studies": "Some books are to be tasted, others to be swallowed and some few to be chewed and digested". Bacon would no doubt have agreed that all three categories could have been accommodated in the one book under review here, for it caters for three separate types of reader—physicists working in fields other than electron optics, those engaged in electron optical design, and those actively engaged in this research field and pondering over its problems.

Before discussing how the book meets these needs, it is as well to trace its origin and purpose. The monograph on "Electron Optics" appeared as a Cambridge Physical Tract in 1939. At that time the subject as such had been recognized as a new and developing branch of 'electron physics' for about a decade, and its general basic principles had been formulated. These had been stated with conciseness and clarity in the first edition; so much so, in fact, that it formed an excellent introduction to the subject for all those engaged in research and development work involving the principles of operation and design of electron devices of many kinds. Since that time the importance of the subject has been widely recognized in both academic and industrial fields, and a considerable volume of work has appeared,

enlarging upon and extending the field of application. The extent of this development can be gauged by a comparison between the first and the present second edition, in which the book has expanded to approximately six times its original size and includes some five hundred references to original papers.

The task of co-ordinating so extensive a field is no easy one. It requires a great deal of selective judgment and critical ability on the part of an author, as well as an exceedingly wide acquaintance with fundamental work in borderline fields; these are necessary in order to present the subject with coherence and unity. These qualifications are happily to be found in Prof. Klemperer, who has himself contributed a large amount of important work in the subject of which he writes.

While it can generally be said that the pattern of the subject-matter has now become formalized, yet the author introduces and develops many topics in an original way; in many instances there is evidence of an individualistic outlook which is highly stimulating to those actively engaged in research. The great merit of the book is that, as stated earlier, it can be used profitably by all types of worker. The novice will find a clear description of all the basic properties of focusing fields—electrostatic and electromagnetic—as well as their defects, treated mainly from the experimental point of view. The initiated will welcome good discussions on the effects of space charge on round and flat beams and fields, as well as a separate chapter under the heading of "Emission Systems" which deals adequately with the important characteristics of 'electron guns'. The chapter on emission systems with line focus brings to the reader's notice the characteristics of recent developments on 'box' and 'double lipped' lenses and their application to the design of X-ray tubes, triode and beam power valves and photomultipliers; while that on 'deflecting fields' will be of special interest to television engineers because of the detailed treatment of inherent errors and their correction.

The experimental physicist engaged on problems of 'separation analysis' will find much useful information on cylindrical and spherical condenser focusing systems, as well as on the properties of magnetic sector fields, and mass and beta-ray spectrometers (their dispersion and resolving power).

The final chapter, on applications in industry and research, is in a sense a consummation of all that has gone before, for it gives an account of the various fields in applied physics enriched by the application of knowledge of principles established earlier. Here are to be found clear descriptions of such important devices as television pick-up tubes, scintillation counters, image converters, electron microscopes, electron accelerators, storage tubes, etc.

On the whole, the book is authoritative and shows a good balance by skilful blending of the old and new. It gives a just emphasis to those topics which are in process of development, indicates and assesses the importance of complicating factors in interpreting fundamental results and will have the effect of stimulating the more advanced worker in his researches. It also carries much useful information in the form of curves, for the designer of systems who requires them to have a certain 'quality'. It has a good index and copious references to original sources. The latter could be improved in the bibliography by giving the page number in place of the chapter.

L. JACOB

Organic Chemistry

The Chemistry of the Compounds of Carbon. By Prof. Lucius Junius Desha. Second edition. Pp. xvi+595. (London: McGraw-Hill Publishing Co., Ltd., 1952.) 55s. 6d.

PROF. L. J. DESHA has written an introductory course for university students, including those not continuing the study of chemistry. His aim is not to make a review of the vast amount of factual matter, but rather to help students to acquire an understanding of fundamental principles so that they may look up facts with intelligence.

Accordingly, in place of the usual approach he selects topics which serve his purpose and arranges them in a sequence so that concepts and terminology are gradually introduced. Then, as each theoretical point, such as resonance or reaction mechanism, is met, Prof. Desha gives a clear, elementary and yet, for this stage, sufficiently full exposition of it. Again, in pursuance of his plan, aromatic compounds are presented to the reader in as early as the fifth of the twenty-seven chapters; thenceforward alkyl and aryl compounds are considered together. Petroleum and coal, as the chief modern sources of industrial products, fill the sixth chapter. Prof. Desha devotes three chapters to polyfunctional compounds, one to dyes and one to heterocyclic compounds. In Chapter 27, on organic chemistry and life, substances such as cortisone and penicillin are not merely mentioned but more than a page is given to each.

This is a brightly written book, effort-requiring yet socially and intellectually interesting. It is obviously the work of an experienced teacher. The new edition is thoroughly up to date and affords a sound introduction to organic chemistry for all kinds of students.

G. F.

Manures and Fertilisers

By Dr. A. M. Smith. (Nelson's Agriculture Series.) Pp. xii+276. (London and Edinburgh: Thomas Nelson and Sons, Ltd., 1952.) 15s. net.

THE student who takes up this book as a guide to the study of manures and fertilizers will find himself in good hands. Dr. A. M. Smith, of the Edinburgh and East of Scotland College of Agriculture, is a teacher and advisory worker of long experience who has many valuable points of contact with the fertilizer industry and has closely observed the changes in fertilizer policy operating during and after the War. So far as the chapter headings are concerned, the book follows conventional lines: it starts out with the general principles of plant nutrition, follows with a discussion of the various bulky and concentrated organic manures, and then turns to the common nutrients and trace elements. The treatment of these topics is exceedingly good.

Dr. Smith wastes no words; in the compass of some two hundred and sixty pages he has brought together an impressive amount of information that is reliable and up to date. Particularly useful sections deal with composts, sewage sludge and town refuse, while the section on poultry manure contains information not easily obtainable in compact form elsewhere. In dealing with the fertilizer materials, a note is provided on the natural reserves of raw materials, and the reader obtains a clear outline of the manufacturing processes without becoming bogged down in technical detail. Sidelights are thrown on the fertilizer salts used in other countries—a useful point since British materials are comparatively few. The chapter on trace elements is

well done and put in its proper perspective, and it is emphasized that the diagnosis and treatment of deficiencies is a specialist's job. The broad lines of fertilizer utilization on the various crops is the subject of a lengthy chapter.

Running through the book there is a streak of agricultural common sense which is not always apparent in publications of this kind.

Rockets, Missiles, and Space Travel

By Willy Ley. Pp. xii+436. (London: Chapman and Hall, Ltd., 1951.) 30s. net.

THIS is the second English edition of the author's book published in 1948 under the title "Rockets and Space Travel" (see *Nature*, 163, 820; 1949). The new edition has been very largely rewritten and amplified; the ground covered remains essentially the same, but the material has been rearranged. The most important addition is an account of recent American developments in rocketry carried out in New Mexico at the White Sands Proving Ground—a site established in February 1948 for the testing of long-range rockets. The first projectiles fired here were German V2's, which were later followed by American missiles of a similar character such as the 'Aerobee' and 'Viking' rockets. Military rocket research in Great Britain, which dates from 1934 and was well under way in 1937, is described more fully than in the first edition. It is unfortunate, but unavoidable, that official reticence should have created the impression that British achievements in this field have been of minor importance. There are several appendixes containing a varied assortment of numerical and factual information on all aspects of rocket development and navigation. Finally, the valuable bibliography has been considerably extended.

R. A. RANKIN

Statistical Tables for Biological, Agricultural and Medical Research

By Sir Ronald A. Fisher and Dr. Frank Yates. Fourth edition, revised and enlarged. Pp. xi+126. (Edinburgh and London: Oliver and Boyd, Ltd., 1953.) 21s. net.

THIS standard work, first published in 1938, is indispensable for anyone seriously interested in statistics, and most such persons already possess one of the earlier editions and will want to know how much new matter now appears. The Roman numbering of the tables is retained with Arabic appendages for new tables. Since the first edition, Tables V, VIII, XI, XVII and XXIII have been improved, and ten new tables have been added. These deal with the significance of the difference between means when the variance cannot be pooled, with the fiducial limits in a binomial distribution, with bacterial counts estimated by dilution until there is none left, and with tests for periodic components. There are two new tables for geneticists, giving scores for linkage data from intercrosses, and segmental functions. There is also a table of the normal probability integral and two tables of random permutations.

The explanations and examples in the introduction are very valuable for beginners and generally adequate; but those dealing with Tables VIII 3 and XXIV might perhaps be amplified with advantage. The authors have done much not only for the professional statistician, but also for the weaker brethren, though they refuse to provide the simplified *t*-test based on ranges. It was clearly impossible to include everything.

J. H. GADDUM

ELECTRON MICROSCOPIC OBSERVATIONS ON BACTERIAL NUCLEI

By Dr. J. R. G. BRADFIELD
Cavendish Laboratory, Cambridge

WIDELY divergent views have been held regarding bacterial nuclei. Some investigators have denied their existence; others have gone to the opposite extreme and suggested that bacteria consist of naked nuclei. In fact, however, there has long been strong evidence (reviewed by Robinow, Bisset and Knay¹) for the existence in bacteria of bodies equivalent in many respects to the nuclei of animal and plant cells. Apart from the size problem, the chief difficulty in the demonstration of bacterial nuclei by the light microscope has been the existence in the cytoplasm of these organisms of abundant ribonucleic acid, which often stains strongly with 'nuclear' stains, thus masking the nucleus itself, or else creating the impression that nuclear material is uniformly distributed throughout the bacteria. When the ribonucleic acid is removed by dilute acid, or by ribonuclease², nuclei can often be demonstrated. As regards work with the electron microscope, progress has been hindered by at least three factors: (a) absence of specific staining methods; (b) doubts as to whether bacterial nuclei might be expected to appear dark or light in electron micrographs; (c) the considerable opacity of whole unstained bacteria (especially cocci) to electrons, in the normal current working-range of 50–100 kV.

Techniques

These obstacles have been to some extent overcome by two recent developments: (a) thin sectioning; (b) a modified Feulgen stain suitable for use with the electron microscope. The sections described here were cut on a modified Cambridge rocking microtome at a thickness of approximately 0.035 μ from bacteria fixed in most cases in buffered osmium tetroxide solutions and embedded in poly-*n*-butyl methacrylate³. In the normal Feulgen technique, mild acid hydrolysis produces from deoxyribonucleic acid an insoluble aldehyde, which re-colours Schiff's reagent and takes up the purple dye so produced. This dye cannot, however, be detected in the electron microscope. Hence, in the modified Feulgen technique, details of which will be published elsewhere, the aldehydes produced by acid hydrolysis of deoxyribonucleic acid are allowed to reduce ammoniacal silver hydroxide, thus depositing metallic silver, which can easily be detected in the electron microscope. A similar technique has already been employed by Bretschneider⁴, on the rather unrewarding heads of mammalian spermatozoa, the extremely dense Feulgen-positive contents of which still defy cytological analysis. Our procedure is rather simpler and based on experience in the use of ammoniacal silver for staining connective tissue. Our observations have so far been limited to two kinds of bacteria—the 'Oxford' staphylococcus from the National Collection of Type Cultures, and a paracolon bacillus (*Paracolobacterium* sp.) morphologically similar to, but slightly smaller than, *Escherichia coli*. In each case, organisms from old resting slopes were compared with actively growing organisms freshly suspended in a 'Difco' broth for four hours at 37° C.

Staphylococcus aureus

Intact staphylococci (Fig. 1) are extremely dense to 70 kV. electrons (even when formal-fixed and unshadowed) and little or no detail of their internal structure can be observed. In sections (Fig. 2), the actively growing coccus (average diameter 0.5 μ) shows a well-defined, spheroidal, central area (0.2–0.25 μ in diameter), which in osmium-fixed cells is of markedly lower electron-scattering power than the periphery. This clearer central area contains bodies remarkably similar in form and arrangement to chromosomes (Fig. 2) and nucleoli (Fig. 3), though it would be rash to identify them as such without much further study.

The modified Feulgen stain (Fig. 4) shows that most—probably all—the deoxyribonucleic acid is localized in these central bodies. The latter, therefore, have both the morphological and the chemical characteristics of animal and plant nuclei and may properly be called bacterial nuclei.

Several kinds of control are run for the modified Feulgen staining method, including the normal Feulgen control in which the preliminary acid hydrolysis is omitted. In general, such controls confirm the validity of the method, though further critical investigation along established lines⁵ is needed. One difficulty which we hope to overcome is the random precipitation of silver granules during staining, common to most ammoniacal silver techniques; this probably accounts for the small deposits around the extreme periphery of the bacterium (Fig. 4), which was stained whole before sectioning. (It would certainly be unjustifiable at present to regard them as evidence of peripherally situated deoxyribonucleic acid.)

Although the boundaries of the nucleus are quite distinct, we have as yet seen nothing which could clearly be identified as a nuclear membrane. In a dividing staphylococcus the nucleus elongates, becoming dumb-bell-shaped, and nips into two. The two daughter cells often remain associated for some time in the familiar 'diplococcal' stage, separated by a double cell-wall; but under our conditions of growth, four-cell aggregates do not occur. The relatively uniform distribution of chromatin throughout the dividing nucleus (Fig. 5) argues against the existence of true mitosis; but since it is by no means certain that there exists a full nuclear apparatus of chromosomes, nucleoli and nuclear membranes, it is premature to make detailed comparisons of division mechanisms.

Paracolon Bacillus

An actively growing paracolon bacillus, fixed in a buffered osmium tetroxide solution, possesses a large, irregular, ellipsoidal central region of low electron-scattering power (Figs. 6, 7). In a bacillus 2 μ long and 0.8 μ wide, this clearer central zone is about 1.5 μ long and 0.4 μ wide. The modified Feulgen stain (Fig. 8) shows that the deoxyribonucleic acid is localized in approximately the same region. This suggests that, as in the staphylococci, the central clearer region in the osmium-fixed organism is the nucleus.

(1) Whole staphylococcus, shadowed 30° to horizontal. (2-5) Sections of actively growing staphylococcus: (2) probably chromocomes in cell approaching division; (3) probably nucleolus; (4) modified Feulgen stain, the central cluster of silver granules, indicating that the nucleus is rich in deoxyribonucleic acid; (5) dividing nucleolus. (6) Longitudinal section, and (7) oblique transverse section, of actively growing paracolon bacilli. (8) Longitudinal section of old, resting bacillus. (9) Longitudinal section of old, resting bacillus. (8) and (10) Modified Feulgen stain showing (in whole bacilli) large nucleus in non-dividing cell (8) and smaller, more compact nuclei in two recently formed daughter cells (10). Magnification: each scale represents 0.5 μ .

The nucleus of the bacillus is much larger (relatively and absolutely) than that of the coccus, the nucleocytoplasmic ratio being about 1 : 2 for the paracolon bacillus and 1 : 10 for the staphylococcus. Like those of the cocci, the nuclei of the bacilli appear to contain chromatin threads and nucleoli; but detailed interpretation is complicated by the existence of fingers of cytoplasm protruding into the nuclei, the latter being much less distinct and compact than in the cocci. This irregular form is greatly accentuated in older, resting bacilli (Fig. 9), where the nuclei ramify through the cytoplasm like the giant branching nuclei in the silk glands or ovarian nurse cells of insects*. In these remarkable metazoan cells nuclear branching is associated with great cell volume and very active protein secretion; as they grow, their initially spherical, orthodox nuclei ramify throughout the cytoplasm—to some extent preserving the balance between nuclear surface and nuclear volume which is thought to be necessary for the nucleocytoplasmic interchanges involved in protein secretion. The small and inactive resting bacilli present exactly the reverse situation, and their branched nuclei arise by quite a different sequence of events. As the bacteria age there occurs what might almost be described as an 'atrophy' of the nucleus—the cytoplasm increasing in bulk and pinching the ellipsoidal nucleus of the young, actively growing bacterium into the shrunken, branching, aged form; the latter is, of course, smaller in volume than the young nucleus from which it has come—in contrast to the branched silk gland nuclei, the volume of which greatly exceeds that of the young nuclei from which they arise.

The reason for the uneven shrinkage of these bacterial nuclei is by no means settled; but it may be related to the fact that the nuclear membrane (if

such exists) is rather tenuous and difficult to distinguish, in marked contrast to the distinct, usually double, nuclear membranes, some 250 A. thick, observed in sections of many animal and plant cells. Only in dividing paracolon bacilli (Fig. 10) have we observed nuclei as compact, well defined and strongly Feulgen-positive as those of staphylococci.

Paracolon bacilli (like *Escherichia coli* and unlike staphylococci, Fig. 1) flatten sufficiently when mounted whole on electron-microscope specimen grids to allow considerable penetration by 50–100 kV. electrons. It has long been known that carefully fixed, whole bacilli often show irregular 'clearer centres' surrounded by a dense peripheral layer, and these clear areas have, without very convincing evidence, been called 'nucleoids'. Our observations confirm this view. Most of the clear areas observed in the intact flattened bacilli undoubtedly result from the large central vesicular nuclei. Indeed, there may well be a correlation between size, or nature, of nucleus and susceptibility to flattening, for the paracolon bacillus with its large vesicular nucleus, presumably containing abundant nuclear sap, is drastically flattened by surface tension forces during drying, even when it remains viable; whereas the staphylococcus, with a nucleus which is both relatively and absolutely much smaller than that of the bacillus, usually preserves its original (nearly spherical) shape very well during drying (Fig. 1). Of course, flattening is also much affected by the shape and nature of the cell wall.

Conclusion

Finally, it is noteworthy that, in contrast to their elaborate nuclei, the two species studied showed little conspicuous structural differentiation in their

cytoplasm. The latter was of fine, granular appearance, with occasional clusters of denser granules (150–400 Å. in diameter) in the polar regions of the bacilli, but no true mitochondria. Dividing cocci showed clear indications of the cytoplasmic vacuoles associated with ingrowing cell walls as demonstrated by Chapman and Hillier for *Bacillus cereus**. (See also Birch-Andersen, A., Maaløe, O., and Sjöstrand, F. S., *Biochim. Biophys. Acta*, 12, 395 (1953), whose paper on electron microscopy of sectioned bacteria appeared after the above was submitted for publication.)

Our main interest, however, has been in the nuclei, both because of their controversial status and because of their possible significance for studies on the evolution of the nuclear apparatus of higher organisms*. As regards the existence of bacterial nuclei, our observations confirm and extend the already strong evidence for the presence in bacteria of bodies which in two respects—chemistry and morphology—have much in common with the nuclei of animals and plants. There certainly are differences, for example, the degree of development of the nuclear membranes, but in the present state of knowledge the differences seem less conspicuous than the similarities.

The third major criterion of nuclear identity is behaviour at cell division. It is in this respect that bacterial nuclei appear to differ markedly from animal and plant nuclei, and from this point of view, therefore, they may be of outstanding interest for studies of nuclear evolution. It is perhaps a forlorn hope that the evolution of the protoplasmic organelles of animals and plants can ever be traced by study of modern micro-organisms. But at least it may be possible, without prejudicing any evolutionary issues,

to distinguish three main levels of 'nuclear' organization (excluding those small viruses which contain no deoxyribonucleic acid): (a) co-existence of deoxy- and ribonucleic acid without such structural adjuncts as chromosomes, nucleoli and well-defined nuclei, clearly distinguishable from cytoplasm—that is, the state of affairs which presumably exists in many small and medium-sized viruses; (b) localization of deoxyribonucleic acid and nuclear ribonucleic acid on special structures (chromosomes and nucleoli) within a moderately well-defined nucleus, which, however, divides amitotically—the condition characteristic of the bacteria here described and possibly of some large viruses; (c) the animal and plant condition, in which a fully differentiated nucleus divides by mitosis. However, great refinements of cytochemical techniques are needed before the wide variety of micro-organisms already recognized can be adequately surveyed and classified from this point of view.

I am indebted to Dr. R. M. Fry and Mr. R. C. Valentine for supplying me with the bacterial cultures used in this work.

FISHERIES SURVEY OF THE MAURITIUS-SEYCHELLES AREA

AS the result of a recommendation in 1945 by Dr. J. F. G. Wheeler, a Colonial Development and Welfare Research Grant was made available for a survey of the fisheries resources of the Mauritius-Seychelles region of the Indian Ocean. The survey was carried out during the two years 1948–49 by Dr. Wheeler and Dr. F. D. Ommanney, and a comprehensive report has now been published*.

Between the Seychelles and Mauritius and forming with them an arc of a circle, the centre of which, six hundred miles away, is the north end of Madagascar, there is a chain of shallow banks which, except for a few isolated inlets, are never uncovered by any tide. The object of the survey was to assess the potential fish resources on and around those banks. The work was carried out mainly in a 70-ft. Scottish-type fishing vessel (M.F.R.V. 1), which made forty-two cruises providing approximately 286½ hours of fishing time. Ancillary observations were made in a schooner and certain other craft from the Seychelles and in small boats and pirogues at Mauritius.

It was found that the only fishable waters for demersal fish are on the banks themselves, as their edges fall away precipitously into great depths. Generally speaking, the best catches were made in

depths of 8–42 fathoms, and the hand-line proved to be the most effective fishing instrument. It was, in fact, demonstrated that catching-rates by the simple, inexpensive and fool-proof method of hand-lining equalled those of trawlers using complicated and expensive trawling gear in normal trawling areas.

There are some 3,300 sq. miles of fishable water within an overnight run from Mahé (Seychelles) and 7,500 sq. miles within three days 'steaming' distance at 8 knots. There is very much less fishable water within the same distance of Mauritius; but the extensive St. Brandon and Nazareth Banks are not more than four days 'steaming' distance away.

Pelagic fishes, strangely enough, were also found to be almost entirely restricted to waters inside the 100-fathom line over the banks and close inshore around the islands. These consisted of a wide range of species from giant sailfishes and swordfishes down to mackerels, anchovies, sardines and the like. No method of capturing any of these on a paying commercial scale was discovered, so pelagic fishing is considered to hold fewer prospects of profitable development than bottom fishing.

The demersal fish resources of the region, on the other hand, are regarded as exploitable and adequate for all foreseeable local needs, and there could well be an exportable surplus if an outlet on the East African mainland could be found and developed.

At present the fish stocks of both the Mauritius and Seychelles areas are exploited only in very small

measure over restricted areas near the inhabited islands. "In due time, says the report, development will come, "but the pattern of its realization is for others to decide". That, of course, must be so, for both Dr. Wheeler and Dr. Ommanney have now left the region; but it would have been helpful if, out of their knowledge and experience, they had offered more precise guidance to those whose lot some day it will be to do the developing. On one point, however, the report is quite clear and emphatic—any power-driven craft that may eventually be used for either fishing or further research on the grounds surveyed must be well-found, mechanically reliable, and carry really competent engineers. Wheeler and Ommanney's survey was beset with far too many avoidable difficulties and disappointments due to machinery failures. In the words of the report, their cruises went forward "under the urgency of impending break down". This applied not to one cruise only, but to all of them, for in the summarized log of the forty-two cruises there are no fewer than twenty-nine entries relating to mechanical failure of one kind or another, arising largely from unskilled attention.

The authors are very well aware that many of their conclusions are based on data that are regrettably 'thin'. In view of the inadequate facilities with which they were provided and the difficult conditions in which they worked, this is not surprising. What is remarkable is that so much was accomplished in spite of the difficulties. This was entirely due to the calibre of those in charge of the survey, and especially to the skill and competence of Skipper Davies, captain of M.F.R.V. 1, who was no less expert in the engine-room than in the wheelhouse; it was due to his skill that on every occasion of machinery failure emergency repairs were made and "the long drift to Africa never eventuated". The measure of the

hazards under which skipper and scientists worked (due to the ever-present threat of machinery breakdown) may be gauged from the fact that out of sight of land no other ship of any kind was seen during the entire commission and no contact was possible with either Seychelles or Mauritius on the effective range of their radio-telephone. In short, this survey by Wheeler and Ommanney was a truly heroic enterprise carried out in conditions that no one in an officially sponsored project of this kind should be asked or expected to contend with.

It will be the fervent hope of all those in any way connected with Colonial fisheries development and research that the Colonial Office and its advisers will pay particular heed to those sections of the Mauritius-Seychelles report that emphasize the importance of mechanical efficiency in sea-going vessels. The M.F.R.V. 1 was placed in the "willing but inexperienced hands of local mechanics", and the survey suffered accordingly. Fisheries development in Colonial territories must depend in large measure on power-driven craft. To maintain them in good and reliable working condition, where ordinary servicing arrangements are either poor or entirely lacking, demands engineering skill of the highest order. To attract engineers of the right calibre into such service requires that both salaries and working conditions be really attractive. Salaries but little higher than those obtainable in the United Kingdom or in other less-exacting posts will attract only low-grade talent with its attendant low efficiency. Such parsimony is entirely false economy. True economy lies in attracting and keeping staff of such quality that worth-while results will be obtained despite difficulties. Projects that flounder or founder through lack of talent in those entrusted with the work are wasteful in the extreme, no matter how tight-fistedly they are financed.

G. A. STEVEN

THE HOXNE INTERGLACIAL RECONSIDERED

By R. G. WEST

Subdepartment of Quaternary Research, Botany School, University of Cambridge

THE Interglacial deposits at Hoxne, Suffolk, occupy a critical position in the Pleistocene stratigraphy of the British Isles. They directly overlie the Kimmeridgian Boulder Clay, contain an Acheulean industry and are covered by deposits of a later glaciation. The dating and the stratigraphy of the deposits are therefore of great importance. New evidence concerning both has recently been obtained by the application of pollen analytical methods and by an extensive programme of boring.

The deposits have been described in detail by Prestwich¹, Clement Reid² and Reid Moir^{3,4}. The accepted scheme of stratigraphy is based on the work of Clement Reid and Reid Moir. The succession described by Clement Reid and his climatic inferences from the plant remains are shown in Fig. 1 a. Later, Reid Moir described sections in the Oakley Park pit which showed that the Palaeolithic Loam rested directly on the Kimmeridgian Boulder Clay and was overlain by a deposit he believed to be glacial, and that it contained a temperate fauna and flora. He accepted Clement Reid's scheme of the stratigraphy and considered the Palaeolithic Loam or so-called "upper temperate brickearth" to be younger than

the beds B, C, D and E of Clement Reid, although it lay directly on the boulder clay. He was then able to complete the climatic succession to the top of the deposits. The resulting scheme of stratigraphy and climatic change, shown in Fig. 1 a, is a composite one, as the beds attributed to a position above the gravel B were described by both Clement Reid and Reid Moir from sections at the north and west faces of the Oakley Park pit, whereas the older beds B, C, D and E were described from the south-west corner of the Old Brickfield, on the opposite side of the Eye-Hoxne road, where the full presumed sequence could not be seen.

The pollen diagram obtained from an excavated section on the west face of the Oakley Park pit, at point 1 in Fig. 1 b, is exactly similar to the diagram obtained from the cores of a deep boring made at point 2, Fig. 1 b, in the south-west part of the Old Brickfield. The similarity of the pollen diagrams shows that Clement Reid's Palaeolithic Loam and bed E are of the same age. A large number of borings made in the area gave the stratigraphy shown in Fig. 1 b. Both the pollen analytical and stratigraphical evidence prove that there is only one

temperate horizon in the Inter-glacial deposit. The error made by Clement Reid and Reid Moir in differentiating the Palaeolithic Loam from the bed *E* was probably due to the difference in their appearance, for where bed *E* rises to near the surface, as it does in the north and west parts of the Oakley Park pit, it is weathered to the mottled colour characteristic of gley horizons of waterlogged soils.

The pollen diagrams from the beds *C*, *D* and *E* of Clement Reid show a succession from late-glacial conditions at the base of bed *E* to temperate conditions at a higher level. There is a marked and sudden change in the diagrams at the interface of beds *D* and *C* which probably represents an erosional unconformity, so that the diagrams do not cover the whole Interglacial period. The climatic inferences from the pollen analytical results are shown in Fig. 1*b*.

The thick and compacted lacustrine beds must represent a long period of deposition. The pollen diagram indicates that they probably belong to the Great Interglacial (Elster/Saale or Mindel/Riss Interglacial). The diagram is not of the type characteristic of the Last Interglacial in north-west Europe. In the presence of an *Abies* (silver fir) zone after the temperate deciduous forest phase it resembles the diagram from the Clacton Channel¹, but differs from that of the Cromer Forest Bed given by Woldstedt². The deposits also contain *Azolla filiculoides* Lam.³, a plant found in many deposits in north-west Europe which are dated to the Great Interglacial on geological evidence, but which has not yet been found in the Last Interglacial. There is no doubt that the basal boulder clay immediately precedes the lacustrine deposits, suggesting that this boulder clay probably belongs to a late part of the Elster Glaciation of northern Europe. The lithology and fabric of the overlying clayey sand and gravel indicate that they are in a primary position and were not deposited by solifluxion processes. The period of their deposition would then be the Saale.

The relation of the archaeology to the stratigraphy has been examined closely and there appears to be evidence for a single archaeological horizon in place in the temperate brown clay-mud (bed *E* of Clement Reid), at the level marked X in Fig. 1*b*. It is probable that the Acheulean industry is referable wholly or in part to this horizon, an attribution conforming with Baden-Powell's recent assessment of the material as 'Late Middle Acheulean'⁴.

A full account of the stratigraphy, palaeobotany and archaeological stratification is in preparation and

Fig. 1. Diagrammatic west-east sections through the western part of the Home deposits, showing the interpretation of the stratigraphical and climatic succession by Clement Reid and Reid Moir (a) and by West (b).

will be published elsewhere, together with some of the consequences for the revaluation of the East Anglian glacial sequence as a whole.

The work has been carried out at the Sub-department of Quaternary Research, Botany School, University of Cambridge, under the supervision of Dr. H. Godwin, during the tenure of a Nature Conservancy studentship. The deep boring was paid for by the Royal Society of London, and the Suffolk Naturalists' Society assisted in payment for certain of the excavations. We gratefully acknowledge the assistance given by both bodies.

OBITUARIES

Prof. Norman M. Comber

NORMAN MUNDERSON COMBER died at his home in Leeds on December 5, within three months of his retirement from the chair of agricultural chemistry and the office of head of the Department of Agriculture in the University. His retirement brought to a close a period of forty years service in the University of Leeds, during the last four and a half years of which, though beset by serious illness, he nevertheless continued with conspicuous courage to play a full part in the affairs of his Department. His death will be regretted by agricultural scientists and agricultural educationists everywhere, and not least by his many friends who had hoped that he might enjoy a well-earned period of retirement; and all will wish to extend their sympathy to his widow who, with a son and daughter, survives him.

Comber was a native of Brighton and graduated in 1909 after studying chemistry at the Royal College of Science, London. His first professional appointment was at the East Anglian Institute of Agriculture at Chelmsford, where his life-long interest in soil science was awakened and whence, in 1913, he came to the University of Leeds to join the staff of Prof. Charles Crowther, whom he succeeded in the chair of agricultural chemistry in 1924. In 1932, on the retirement of the late Prof. R. S. Seton, he became head of the Department of Agriculture and was responsible for its direction until his retirement, under the age limit, in September last.

Comber's researches, which have brought distinction to his Department and the University, were chiefly concerned with the aggregation of soil particles and were published in numerous papers in various scientific journals. His name will long be remembered in connexion with the 'Comber test' which he devised for the detection of sourness in soils. His research activities, however, were latterly increasingly limited by administrative responsibilities involved in the direction of a department which was concerned not only with intra-mural university work but also with extra-mural advisory and educational activities among farmers in the county of Yorkshire until, in 1946, these latter became the responsibility of the National Agricultural Advisory Service and the county councils, respectively. He was deeply interested in agricultural education, and his wide and varied experience led him to develop clear and strong views concerning the training of agriculturists and agricultural scientists. He was convinced that the optimum training for the agricultural scientist was one based upon pure science, a conviction which led in recent years to the establishment in the University of Leeds of postgraduate courses in agricultural sciences for pure science graduates. Nor was his interest restricted to education at the university-level, for he was responsible for the successful organization of day-continuation classes in agriculture for school-leavers in Yorkshire and did pioneer work in the establishment of the Yorkshire Federation of Young Farmers' Clubs.

During his forty years service in the University of Leeds, Comber played a full and active part in its affairs, as member of Court, Council and Senate, dean of the Faculty of Technology, chairman of the Board of Science and Technology, president of the Priestley Club and member of many committees. He had a profound interest in students and their welfare

which continued long after they had left the University. He was actively associated with many scientific and professional bodies. As secretary and later chairman of the Yorkshire Section of the Society of Chemical Industry, chairman of the Yorkshire Branch of the Rural Community Council, member of council and of the executive committee of the Rural Community Council, chairman and afterwards treasurer of the Agricultural Education Association, he gave ungrudgingly of his time and energy. He was a distinguished foundation member of the International Society of Soil Science, and had actively participated in its meetings not only in Great Britain but also in Italy, Hungary, the U.S.S.R. and the United States. The British Association for the Advancement of Science recognized his eminence as an agricultural scientist by electing him president of Section M in 1949, and shortly before his death the Agricultural Education Association, with which he had been actively associated since 1912, conferred honorary membership upon him in recognition of his outstanding services to agricultural education.

For many years Comber gave devoted service to the Baptist Church as lay preacher and deacon, and in 1938 the Baptist community in Yorkshire conferred upon him the highest honour they could bestow by electing him to the presidency of the Yorkshire Association of Baptist Churches.

All who studied under Comber or worked in close association with him will remember his genial personality, his acute, agile and critical mind, his meticulous attention to administrative detail and his mastery of both the spoken and written word; and they will recall his unquenchable sense of humour, which was evident even latterly in the face of a physical affliction which he bore uncomplainingly and with the greatest fortitude and courage.

J. S. WILLOOX

Prof. J. O. Wilhelm, O.B.E.

JOSEPH OSCAR WILHELM, director of the Research Council of Ontario, died in Toronto General Hospital on November 19, after a short illness. His death at the age of fifty-four has cut short a distinguished career.

Prof. Wilhelm was born in the village of Shakespeare, Ontario. Educated at the University of Saskatchewan and the University of Toronto, he lectured in the Physics Department of the latter university from 1927 until 1948. He served, on leave of absence in the Second World War, as technical assistant to the president of Research Enterprises, Ltd., with the National Research Council of Canada, with the R.C.A.F. as director of operational research, and with the federal Department of Reconstruction.

Following the War, he was secretary of the Ontario Research Commission during 1945-48, the work of which resulted in the establishment of the Research Council of Ontario. As director of the Council since 1948, his energy and ability were largely responsible for the organization of more than two hundred and fifty representatives of industry, government and universities in various research committees concerned with technical problems affecting Ontario's natural resources and the supply of scientists. In this work his deepest faith lay in new generations of students whose possibilities inspired his efforts.

In addition to many other affiliations, both in community organizations and professional groups, he was first vice-president of the Royal Canadian

Institute and chairman of the board of Knox Theological College, Toronto. He was well known to many scientists in Britain and the United States. A recognized authority on low-temperature physics, he was equally at home with men and ideas. His bent for organization sprang from his imaginative grasp of problems outside his own field, his fresh and stimulating spirit, and his capacity for friendship. Always willing to attempt the difficult, he was devoted to the public welfare. His early death was a shock to his many colleagues and friends, a great loss to Canada and the community in which he lived.

In 1927 Prof. Wilhelm married Nan Kathleen Munro of Saskatoon. He is survived by his widow, a son Donald who is at present in England, and a daughter Mildred still attending school.

W. J. MACKEY

Mrs. E. M. Reid

Mrs. E. M. REID, the noted palaeobotanist, died on September 28 in her ninety-third year. The daughter of John Copner Wynne Edwards, of Denbigh, she was educated at Westfield College, and taught mathematics at Cheltenham; she turned to geology and botany after her marriage to Clement Reid, of the Geological Survey, in 1897. Reid was a pioneer in the study of fossil fruits and seeds of the later geological formations, and Mrs. Reid threw herself wholeheartedly into this work, devising or improving techniques for extracting plant remains from peat, and bringing a methodical and highly critical intelligence to the study of the seeds and fruits so obtained. At that time it was by no means generally accepted that specific identifications were possible from isolated seeds and fruits, let alone from imperfect or fragmentary specimens which might have undergone alterations due to incipient fossilization. By a close study of the fruiting organs of living plants, however, the Reids proved conclusively that floral assemblages of the comparatively recent past could be reliably reconstructed from deposits which contained abundant fruits and seeds. Working backwards from Holocene and Pleistocene floras, their joint studies culminated in an extensive memoir on the "Pliocene Floras of the Dutch-Prussian Border" (1915). In 1916 Clement Reid died, only three years after retiring to Milford-on-Sea in Hampshire; his widow remained there for the rest of her life, and with great determination continued her palaeobotanical research. She described preglacial floras from Durham, with an important "Comparative Review of Pliocene Floras" (1920), and from then on was constantly consulted for determinations by botanists and geologists in various European countries.

After being joined by Miss M. E. J. Chandler, Mrs. Reid pressed her investigations farther back into the Tertiary, and in 1928 the British Museum (Natural History) published a volume by the two authors on the Bembridge (Oligocene) flora of the Isle of Wight, based on the a'Court Smith collection which had been acquired for the Geological Department of the Museum. Mrs. Reid was then asked to study, in conjunction with Miss Chandler, the extensive collection of pyritized fruits and seeds from the Eocene London Clay, which had been in the British Museum for more than a century. Seven years intensive work produced the "London Clay Flora" (1933), which at once took its place as a classic of Tertiary palaeobotany. In the introduction

to these two monographs, and particularly the second, Mrs. Reid analysed with great lucidity the phytogeographical, climatic and evolutionary significance of the European floral succession throughout the Tertiary, as revealed by studies of angiospermous fruits and seeds. Certainty of identification depended on morphological and anatomical structure, which in turn threw light on secular changes of character within genera and families; biogeographical alliances of genera represented in fossil floras showed an increasing correlation in past Tertiary periods with present floras of the Far East, until finally the Eocene of southern England proved to have a tropical flora related to that of the present Indo-Malayan region.

After the work on the London Clay, Mrs. Reid undertook no major commitments, though she published a number of short papers either alone or with Miss Chandler, who lived with her and with whom she continued to discuss further studies on Tertiary floras of southern England. The final results of this prolonged research are now being prepared for publication by the Trustees of the British Museum.

Mrs. Reid and her husband lived most frugally; her life was strictly ordered with a disciplined austerity; she was critical but charming, and could always find time to assist other inquirers. She was devoted to her church and other local affairs, and found solace in reading, particularly books of travel. Her scientific work was the outcome of steady perseverance combined with originality and an analytical mind.

W. N. EDWARDS

Dr. G. H. H. Tate

DR. GEORGE HENRY HAMILTON TATE, who died in Morristown, New Jersey, on Christmas Eve at the age of fifty-nine, was curator of mammals in the American Museum of Natural History, New York. Dr. Tate was born a British subject, on April 30, 1894, in London. He served in the Army during the First World War, and afterwards went to the United States, where, in 1921, he became a field assistant of the American Museum of Natural History. In 1927 he became an American citizen, and in the same year graduated as a bachelor of science of Columbia University, taking his master of arts degree in 1931. In the same year he was appointed assistant curator of South American mammals in the American Museum of Natural History, which post he held until 1942, when he was made associate curator of mammals, and later, in 1946, curator of mammals. In 1937 he was made a doctor of science in the University of Montreal. During the Second World War he served as chief of rubber explorations for the Defence Supplies Corporation at Washington.

During the course of his time at the American Museum, Dr. Tate went on forty-two collecting expeditions, to South America, New Guinea and Australia, as well as to West Africa. These expeditions, many of them carried out in association with Mr. Richard Archbold, led to an imposing series of monographs, those on the Chiroptera, Rodentia and Marsupialia being of particular importance.

Dr. Tate came fairly regularly to England, where his mother still lives, and his work brought him for weeks at a time to the British Museum (Natural History), where the staff of the Mammal Room were always glad to welcome him, together with his wife Eleanor who survives him.

T. C. S. MORRISON-SCOTT

NEWS and VIEWS

Applied Mathematics in King's College, London:
Prof. H. Bondi

THE vacancy in the professorship of applied mathematics at King's College, University of London, created by the departure of Prof. G. Temple to Oxford, has been filled by the appointment of Mr. H. Bondi, at present University lecturer in mathematics at Cambridge. Mr. Bondi entered Trinity College, Cambridge, in 1937 and was placed in the first class (Wrangler) of Part II of the Mathematical Tripos in 1939. His career was prevented from following the usual course by the outbreak of war, during which he engaged in important theoretical and experimental problems for the Admiralty. In 1943 he was elected to a research fellowship at Trinity College, and in 1952 to a staff fellowship.

Mr. Bondi's researches have been in a wide range of topics in mathematical physics, theoretical astronomy, and geophysics. Gifted with the degree of mathematical aptitude one associates with Cambridge and Trinity College, and possessed of a deep appreciation of the philosophical aspects of science, Mr. Bondi found suitable material for the application of his talents in the new ideas in astronomy that had been developing in recent years. His earliest papers were on such subjects as the theory of shock waves, of the mechanism of accretion, and the development of special methods for dealing with the refractory equations that govern stellar structure. In geophysics his work has been concerned with important hydrodynamical problems of the motion of the fluid core of the earth resulting from precession and the retardation of the earth's rotation. More recently, Mr. Bondi's name has been closely associated with the renewed activity in the field of cosmology, and in particular with the hypothesis of the continuous creation of matter, which is generally accepted by astronomers to be one of the most profoundly daring ideas yet introduced in astronomy. Mr. Bondi's wide reputation brings him into considerable demand as a lecturer, and twice during recent years he has been invited to the United States. In 1950 he visited Cornell University with a research appointment, and again in the autumn of 1953 he visited Harvard College Observatory to deliver lectures.

South Wales Laboratories of the British Iron and Steel Research Association:

Mr. D. Luther Phillips

MR. D. LUTHER PHILLIPS, who will retire in February under the age-limit from his post as head of the South Wales Laboratories, Sketty Hall, Swansea, of the British Iron and Steel Research Association, graduated in 1911 with honours in chemistry at the University College of Wales, Aberystwyth, and was later awarded an 1851 Exhibition industrial bursary at Baldwins Iron and Steel Works, Landore, Swansea. During the following years he became successively chief chemist and metallurgist, blast-furnace manager and (in 1928) works manager of the Landore works. In 1931 he was appointed senior research officer to the local steel and tinplate associations at the Metallurgy Department, University College, Swansea, and his work at Swansea on strain age-hardening culminated in a joint paper with Dr. C. A. Edwards and Mr. H. N. Jones on "The Influence of Some Special Elements on the Strain Age Hardening and Yield Point Characteristics of Low Carbon Steels",

which excited much attention, indicating a new and fruitful approach to this problem. In 1946 Mr. Phillips became head of the Laboratories at Sketty Hall, where he has done much to inspire the team working there on problems of coatings and steel surfaces.

Dr. J. Pearson

MR. PHILLIPS is to be succeeded by Dr. J. Pearson, at present head of the Chemistry Department of the British Iron and Steel Research Association. Dr. Pearson graduated in 1933 in the University of London, gaining his M.Sc. a year later for research in organic chemistry, and then joined the Research Department of Tube Investments, Ltd., to carry out work in connexion with the manufacture of steel tubes and allied products. During 1937-46 he was employed in the explosives branch of the Armament Research Department, Ministry of Supply, and obtained his doctorate in 1946 for research work on the polarography of organic compounds. In 1946 Dr. Pearson became head of the Chemistry Section of the Swansea Laboratories of the British Iron and Steel Research Association, where he was largely concerned with problems on the disposal of spent pickle liquor, and was appointed head of the Chemistry Department in February 1950.

Sir James Frazer, O.M., F.R.S. (1854-1941)

JANUARY 1 marked the centenary of the birth of Sir James George Frazer, in whose works a new science, the comparative study of primitive religions, was established. After graduating at Glasgow, Frazer became a scholar of Trinity College, Cambridge, thus beginning his long and happy residence there. He was afterwards elected to a fellowship at Trinity, which was thrice renewed and finally held for life, the total period being more than sixty years. Although his early work was on the classics, he soon turned towards the study of primitive religions, though his interest in the classics remained strong, as witness his five-volume work on "The Fasti of Ovid", published in 1929. In applying the comparative method to the study of religions, his aim was to regard them not as systems of truth or falsehood to be demonstrated or refuted, but as phenomena of consciousness to be examined like any other aspect of human nature. Many of his researches are embodied in "The Golden Bough". This great work developed slowly. As originally published in 1890, it was in two volumes. The second edition, which appeared in 1900, was in three volumes. Research continued, and finally, between 1911 and 1915, the great third edition in twelve volumes was produced. His friend Anatole France said of him: "Frazer nous a donné de l'homme la connaissance la plus vaste et la plus neuve. Il nous a fait entrer dans la pensée des barbares d'aujourd'hui et des temps lointains; il a substitué aux fables que l'homme imagine pour expliquer sa propre origine les premières données d'une science rigoureuse, qui n'existait pas avant lui". When he died in his eighty-eighth year, a life of long-sustained industry had ensured the permanent recording of the results of researches that have a profound significance for mankind.

The B.B.C. "Science Survey": Dr. Archie Clow

On February 4, Mr. Eric Simms is broadcasting in the B.B.C. Home Service on "Badgers: their Vocabulary and Language". This talk will be the 250th to be produced by Dr. Archie Clow, of

the British Broadcasting Corporation, in the series now well known as "Science Survey". This series has proved to be a remarkable achievement. Sir Edward Appleton said at the British Association meeting at Liverpool in 1953 that: "You have not really got to the bottom of the matter yourself if you cannot explain it to the man in the street"; Dr. Clow has always seemed to bear this in mind when selecting his speakers for Science Survey. Nevertheless, he has also always insisted 'on substance in these broadcasts and an absence of 'talking-down' to the listener. Scientific material, even that of immediate human or sociological or industrial importance, is sometimes very difficult material when being prepared for interpretation to the non-scientist, either by radio or through the newspaper press, yet it is possible to hold the interest of a listener or reader once his interest is captured at the initial stages. But this needs careful preparation and handling, and it seems that here Dr. Clow has revealed a genius for production. It is good, therefore, to have the opportunity on this 250th anniversary to congratulate Dr. Clow on his excellent work in scientific exposition and interpretation through the medium of the radio.

Science and Foreign Relations In the United States

WHILE the symposium of papers contributed to the September issue of the *Annals of the American Academy of Political and Social Science* gives a clear factual account of the part that the United States Congress plays in the foreign relations of the United States, it will disappoint those whose hopes had been raised by the appearance of the Berkener report on "Science and Foreign Policy". Following some account of the constitutional position of Congress and of the part it has played before and after 1900, the functions of Congress in foreign relations are explained and then the relations between legislature and executive. Nowhere, however, not even in the concluding discussion of the future of Congress in foreign relations, is any reference made to the recommendations of the Berkener report, and it would seem prudent to conclude that the likelihood of these recommendations being implemented is slight. The influence which science exerts on the foreign policy of the United States in the foreseeable future is likely to be negligible, at any rate until the public discussion of nuclear energy problems considered by Dr. J. B. Conant as desirable is also possible.

Insect Enemies of Western Forests of the United States

A FIELD manual by F. P. Keen on "Insect Enemies of Western Forests" has been issued as a revised edition by the United States Department of Agriculture (Misc. Pub. No. 273; pp. 280; Govt. Printing Office, Washington, D.C., 1952; 1 dollar). It is a very practical illustrated manual covering a wide range of forest insect pests, and written for the use of forest rangers, field-men and others responsible for the protection of the forest resources of the United States. The *raison d'être* is to bring together in summary form published bulletins, articles and records and also unpublished reports. The manual is restricted to insects found in forests west of the Great Plains, roughly the 100th meridian. In dealing with the control of the important bark beetles, of which some details of costs are given, the author correctly says: "At the best, remedial bark-beetle control is only a temporary expedient or a method

of suppressing outbreaks that have been brought about through some interruption or disturbance of the biological balance". The only permanent protection to forests is by the maintenance of the natural balance.

Fossil Water-Ferns

A NOTE in the *Transactions of the Suffolk Naturalists' Society* (8, Pt. 2) describes the discovery of two genera of water-ferns, *Azolla* and *Salvinia*, in interglacial deposits in Suffolk. Both these genera are new to the British Pleistocene flora, but have been found in interglacial deposits on the Continent. *Azolla* was found in the deposits at the classic site of Hoxne, and *Salvinia* in the interglacial deposit at Bobbitt's Hole, near Ipswich. Only the male and female spores of the plants have been found so far. The spores of the fossil *Azolla* are very similar to those of the modern *A. filiculoides* Lam., a species which was introduced into Britain towards the end of the nineteenth century. The species of fossil *Salvinia* has not yet been determined. (See also p. 187 of this issue.)

Potassium Absorption by Growing Root Cells

Using a technique, which is described, R. Brown and P. M. Cartwright (*J. Exp. Bot.*, 4, 11, 195; 1953) have shown that when thin serial sections of maize root, taken from the apex backwards, are immersed in 0.01 N solution of potassium chloride in water and in 2 per cent fructose, absorption of potassium by the distal or tip section, which consists almost entirely of meristematic cells, is abnormally low. This is attributed to the absence of a tonoplast surrounding a central vacuole in the cells of this region. The data for potassium absorption are presented in various ways, but when they are reduced to a unit cell basis they show that, per cell, absorption increases as expansion occurs in the root. This is ascribed to an increasing protein content. It is shown that during cell growth in the root, the cytoplasm differentiates in such a way that absorption per unit protein increases. When sugar is provided, the rate of absorption is always stimulated, though the effect of it on final concentration varies with the extent to which the tissue grows. Although when the root is sectioned the rate of absorption is lowest in the meristem, nevertheless this is the region of highest potassium concentration in the intact root. The mechanisms which may be involved in the different circumstances are discussed.

The Flamanville Granite In Normandy

IN 1894 Michel-Lévy published a memoir on the Flamanville Granite, long regarded as a classic, in which he recorded evidence indicating that the granite had been produced *in situ* from the pre-existing rocks. Dr. N. R. Martin has recently carried out a structural study of the mass (*Quart. J. Geol. Soc.*, 108, 311; 1953), using the techniques originated by the late Prof. Hans Cloos. Dr. Martin considers that the granite was emplaced as a diapir that forced its way through a belt of incompetent rocks—already folded on general east-west axes—which were readily buckled still further and thrust aside. The directions of the primary flow-planes of the granite minerals and of the foliation of the surrounding hornfelses are said to be consistent with the conception that the granite was forcefully intruded through a 'neck' below what is now the eastern side of the mass. As the resulting pluton was

continually fed with magma, it became inflated within a plastic cover, somewhat like an expanding balloon. In contradistinction to earlier views, it is concluded that, although metasomatism, feldspathization and assimilation of stoped blocks have undoubtedly occurred along the contacts, these processes are to be regarded as only incidental to the emplacement of the mass as magma. It is noteworthy that Dr. Martin states that the xenoliths detached by stoping "added to the volume of the magma" and that "their assimilation changed its composition". Thus no attempt is made to solve the space problem by stoping. On the other hand, the hypothesis of shouldering aside the country rocks has a serious weakness which is revealed by the 'balloon' analogy. Balloons frequently burst, and the Flamanville 'balloon' would surely have done so as its roof was torn apart by the underlying expansion. Once volcanic activity began, and that would probably be at an early stage, magmatic pressure would no longer be available for thrusting aside the walls. Speculation apart, however, Dr. Martin has made an important contribution by presenting genuine evidence that the mass is intrusive. Evidently the problem of emplacement is much more intractable than was previously supposed.

Personnel Officers In Industry

An interesting comment on the changing climate in industry is revealed in the annual report of the Institute of Personnel Management for 1952-53. The Institute is an association of men and women concerned with the personnel function of management. In 1922 the total membership amounted to 398; in 1937 this number had increased to 613. By 1942 this total had increased to 1,633 and, by 1952, had leaped to 3,806. The figures are ample evidence of the increased attention which is being paid to the human factor in industry. The report also directs special attention to developments in the retail trade and the continued emphasis on training, especially management training, as well as the extended contacts which have been built up in countries overseas.

National Research Council of Canada: Review for 1953

THE National Research Council of Canada's "Review 1953" (N.R.C. No. 3034; pp. 244+12 plates; Ottawa: Queen's Printer, 1953; 75 cents) gives, as is usual, more detailed and specific information on the work of the Council's laboratories during the year ended December 31, 1952, than is contained in the thirty-sixth annual report of the Council, and includes some later work. It also contains a directory of staff, as of July 1, 1953, arranged by divisions and sections of the Council, covering scientific staff from junior research officers upwards, and particulars of staff serving as representatives of the Council on external committees. Reports of the various committees include particulars of membership as well as, like the reports of several divisions, a list of publications during the year. Of the total staff of 1,955 on July 1, 1953, 535 were scientific, 675 technical, 472 general service and 289 maintenance.

First International Seaweed Symposium

THE proceedings of the First International Seaweed Symposium, held in Edinburgh during July 1952 (see *Nature*, 170, 478; 1952), has now been published (pp. 131; from the Institute of Seaweed Research, Inveresk, Midlothian, Scotland, 1953;

10s. 6d.). The lively contemporary interest in the biology and utilization of marine algae is indicated by the facts that this Symposium was attended by nearly two hundred people from twenty-one different countries, and that it is proposed to hold a second one in Norway in 1955. The fifty-three papers submitted, and abstracted in this report, deal with phyecology, algal chemistry, the commercial utilization of algae, harvesting technology and world resources. The main effects of the report are to indicate the wealth of biological and chemical problems awaiting investigation, to which the attention of students might well be directed, and the fact that substantial contributions are being made in many countries.

Scholarships for Study Abroad during 1954-55

THE British Council has published a booklet giving details of more than a hundred scholarships offered to British students by sixteen foreign countries for study abroad during the academic year 1954-55. The scholarships are intended mainly for graduates and undergraduates of universities in the United Kingdom, but some are also open to those with non-academic professional qualifications. The awards generally provide for free tuition and maintenance, and are tenable for periods varying from four to twelve months. The countries offering scholarships are Austria, Belgium, Brazil, Denmark, Finland, France, Germany, Iceland, Italy, the Netherlands, Norway, Portugal, Spain, Sweden, Switzerland and Yugoslavia. The closing date for receipt of applications varies for each country, the earliest date being March 8. Further particulars and application forms may be obtained by sending a stamped addressed foolscap envelope to any British Council office in the United Kingdom, or to the Controller, Education Division, British Council, 65 Davies Street, London, W.1.

N.Z. National Research Fellowships

THE Minister of Scientific and Industrial Research, New Zealand, has awarded the four National Research Fellowships to be taken up during 1954 as follows: R. W. Burling, a graduate of Victoria University College, who is at present doing research in geophysics at the Imperial College of Science and Technology, London, and will then undertake special research at the National Institute of Oceanography, London; R. A. Couper, a graduate of geology of Victoria University College, who will study palaeobotany at the Sedgwick Museum, University of Cambridge; P. A. Toynbee, a graduate in chemistry and diploma-holder in industrial chemistry of Canterbury University College, who will do research in Britain on the total gasification of sub-bituminous coals at the Birmingham Research Station of the Gas Research Board; H. P. Rothbaum, a graduate in chemistry of Victoria University College, who will study photochemistry at the University of Oxford. National Research Fellowships are offered annually to suitable applicants with postgraduate experience in scientific research to enable them to study in New Zealand or overseas institutions. Each Fellowship is worth £600 a year, with a marriage allowance of £100 a year, and grants of up to £50 for books, fees, etc., and up to £150 for travel are also paid. They are tenable for one year, with possible extension for a further year. The four present recipients, whose ages vary from twenty-seven to thirty-three years, are all members of the New Zealand Department of Scientific and Industrial Research.

Physicists In Britain during July

The Eighth General Assembly of the International Union of Pure and Applied Physics will be held in London during July 7-10 in the rooms of the Royal Society. The business meetings will be attended by delegates from the national adhering organizations of the International Union and by members of the Union's Commissions on Publications and Symbols, Units and Nomenclature; but, in order to profit by the fact that a number of distinguished foreign scientists will be in Britain for the occasion, a number of conferences on physical subjects have been arranged. Under the auspices of the International Union, two conferences will be held during July 13-17: one in Glasgow on experimental and theoretical nuclear physics, under the chairmanship of Prof. P. I. Dee, at which problems of nuclear structure and properties of mesons will be dealt with; and the other in Bristol on the physics of the solid state, under the chairmanship of Prof. N. F. Mott, at which defects in crystalline solids, and particularly their investigation by the use of microwaves and the relation between dislocations and other defects, will for the most part be considered. During the General Assembly of the Union, three lectures arranged by the Physical Society will be given at the Royal Institution by Profs. J. A. Wheeler, E. Amaldi and Charles Kittel on July 7 and 9 (at 4.30 p.m.) and July 12 (2.30 p.m.), respectively. In addition to these events, a small limited meeting on the mechanical properties of metals will be held during July 19-20 in the Department of Metallurgy of the University of Birmingham under the chairmanship of Prof. M. Cottrell, and the International Commission on Electron Microscopy will be holding a meeting in London during July 16-21.

Chemical Society: Anniversary Meetings In Manchester

The anniversary meetings of the Chemical Society will be held this year in the University of Manchester during March 31-April 2. The proceedings will commence with a symposium on "Dynamic Stereochemistry", arranged jointly with the Manchester Sections of the Royal Institute of Chemistry, the Society of Chemical Industry and the Institute of Petroleum. It is hoped that the speakers will include Prof. C. K. Ingold, Prof. E. D. Hughes, Dr. P. B. D. de la Mare, Prof. E. Winstein (Los Angeles, California), Prof. V. Prelog (Zurich), Prof. D. H. R. Barton and Prof. K. Alder (Cologne). Further details of this symposium can be obtained from Dr. M. A. T. Rogers, Academic Relations Department, Imperial Chemical Industries, Ltd., Dyestuffs Division, Hexagon House, Blackley, Manchester 9. On the following day, April 1, there will be the annual meeting of local representatives of the Society, followed at 11.30 a.m. by the Liversidge Lecture, to be given by Prof. H. J. Emeléus, professor of inorganic chemistry in the University of Cambridge, who will speak on "Organometallic Compounds containing Fluorocarbon Radicals". On April 2 the Society will hold its annual general meeting, and then at 11 a.m. the president, Prof. C. K. Ingold, professor of chemistry in University College, London, will give the presidential address. The afternoons of April 1 and 2 will be devoted to visits to industrial organizations, and all three evenings will be taken up with social events. Further details can be obtained from the Society at Burlington House, London, W.1.

Colonial Service: Recent Appointments

THE following appointments have recently been made in the Colonial Service: A. G. Dalgleish (assistant secretary, Office of Member for Agriculture, Kenya), secretary for agriculture and natural resources (general), Kenya; R. F. A. L. Reed (senior agricultural officer, Nigeria), principal of schools, Agricultural Department, Western Region, Nigeria; E. Collins (chemist, Hong Kong), government chemist, Medical Department, Hong Kong; D. A. Frye (senior chemist, Federation of Malaya), chief chemist, Singapore; J. W. Du Preez (senior geologist, Geological Survey Department, Nigeria), assistant director, Geological Survey Department, Nigeria; R. Walls (assistant director, Geological Survey Department, Nigeria), deputy director, Geological Survey Department, Nigeria; C. F. F. Gayle (agricultural officer, Jamaica), senior soil conservation officer, Jamaica; J. H. Houghton (senior agricultural officer, Jamaica), chief agricultural officer (agronomy), Jamaica; E. R. H. Martin (assistant agricultural superintendent, Antigua), agricultural superintendent, Antigua; W. G. Stuart (senior agricultural officer, Jamaica), chief agricultural officer (development), Jamaica; A. D. Swan (meteorologist, Gold Coast), assistant director of observatory, Mauritius; A. K. Auckland, botanist (plant breeder), Tanganyika; T. E. Cobb, agricultural officer, Singapore; M. C. Cronin, J. B. Finney and P. R. MacCrimmon, agricultural officers, Nigeria; K. M. L. Matthews, agricultural officer, Uganda; W. F. Van der Byl Morkel, agricultural officer, Northern Rhodesia; H. Affleck, scientific officer, Federation of Malaya; R. F. Barnes, scientific officer (plant pathologist), Jamaica; P. S. Corbet, scientific officer, East Africa High Commission; C. C. Draper, medical research officer, grade 2, East Africa High Commission; M. J. Holden, scientific officer, Sierra Leone; A. W. Allen, soil scientist, Department of Agriculture, North Borneo; E. W. Fowler, chemist/assayer, Northern Rhodesia; D. A. Livingstone, economist/statistician, Kenya; J. Lucas, fisheries officer, East Africa High Commission; J. Stoneman, fisheries officer, Uganda; G. C. Vickers, veterinary officer, Jamaica; R. A. Wood, chemist, Department of Agriculture, Nyasaland.

The Night Sky In February

New moon occurs on Feb. 3d. 15h. 55m., U.T., and full moon on Feb. 17d. 19h. 17m. The following conjunctions with the moon take place: Feb. 4d. 21h., Mercury 4° S.; Feb. 12d. 05h., Jupiter 4° S.; Feb. 23d. 22h., Saturn 8° N.; Feb. 26d. 05h., Mars 4° N. In addition to these conjunctions with the moon, Mars is in conjunction with Antares on Feb. 25d. 0h., Mars being 5.4° N. Mercury is an evening star, setting at 17h. 45m. and 18h. 50m. at the beginning and middle of the month, respectively; but towards the end of the month it sets about twenty minutes after sunset, when it will be invisible. Venus, an evening star, sets too soon after the sun to be favourably seen. Mars, a morning star, rises about 2h. 15m. throughout the month. At the beginning of the month it lies a little south of γ Libræ, and at the end of the month a little north of α Scorpii (it has already been pointed out that it is in conjunction with this star on Feb. 25). Jupiter, visible throughout the night, sets at 4h. 20m., 3h. 30m. and 2h. 35m. on February 1, 14 and 28, respectively, and is a conspicuous object (stellar magnitude about -2) west of ζ Tauri. Saturn rises at 0h. 50m., 0h.

and 23h. 06m. on February 1, 14 and 28, respectively, and is visible in the morning hours (stellar magnitude about 0.6) north-west of α Libra. Occultations of stars brighter than magnitude 6 are as follows, observations being made at Greenwich: February 10d. 23h. 09.7m., 23 Taur. (D); Feb. 26d. 3h. 15.8m., α Scorp. (R). D and R refer to disappearance and reappearance, respectively.

Announcements

We regret to record the death, which occurred on January 21 at Christchurch, New Zealand, of Lady Rutherford, widow of Lord Rutherford of Nelson.

DR. J. SIKORSKI has been appointed lecturer in textile physics in the University of Leeds.

THE Dunlop Rubber Co. has made a grant of £2,000 a year, income tax paid, for the next seven years to the University of Birmingham, partly for general purposes but mainly to establish a Dunlop Fellowship for research work on the chemistry of high polymers, including natural and synthetic rubbers; provision for technical assistance; and the purchase of apparatus not formally available.

In 1947 the Wellcome Trust made a grant of £5,000 for whole-time research Fellowships in schools of pharmacy in Great Britain, and last year this was increased by a further £1,200 when five Fellowships were awarded and the value of each was raised from £350 to £400 a year. The Trust has now announced that it has set aside a further £10,000. The awarding committee, nominated by the Wellcome Trust and the Pharmaceutical Society of Great Britain, has discretion to award a senior research Fellowship at a somewhat higher rate, tenable for two years on an annual basis and renewable in exceptional circumstances for a third year. Fellows must be registered pharmaceutical chemists in Great Britain, or graduates in pharmacy of a British university.

THE Ministry of Agriculture and Fisheries is offering the following scholarships for rural workers, or the children of rural workers, of seventeen years of age or more: ten senior scholarships, tenable at universities or colleges, for degree or diploma courses in an agricultural subject or veterinary science; sixty junior scholarships and six extensions for existing holders, tenable at farm institutes, for one-year courses. Selection is by interview only. Further information and application forms (to be completed by March 31) can be obtained from the Secretary, Ministry of Agriculture and Fisheries, Room 313, 1 Cambridge Terrace, Regent's Park, London, N.W.1, or from education offices of County Councils.

TRINITY COLLEGE, Cambridge, is offering as in previous years a number of research studentships and Commonwealth exhibitions, which will be tenable from next October. The research studentships, which will normally be worth £375 a year, are open to graduates of universities other than Cambridge, who are not more than twenty-six years of age, with time spent in national service deductible from age, and who have not already been engaged on advanced study or research for more than two years. The exhibitions are for students from universities of the British Commonwealth, who intend to read for an honours degree, and are worth £40 a year. Applications, to be sent through the head of the candidate's university, must reach the Senior Tutor, Trinity College, Cambridge, not later than April 1 for studentships and May 1 for exhibitions.

THE international congress of chronometry organized by the Société Chronométrique de France, which was to have been held in Paris this spring (see *Nature*, November 21, 1953, p. 942), will now be held during October 1-5. Those wishing to read papers should communicate before June 1 with the president of the Society, Prof. R. Baillaud, Directeur de l'Observatoire National de Besançon, Doubs, from whom further information can be obtained.

THE Society for Endocrinology is arranging a symposium on "The Technique and Significance of Estrogen Determinations", to be held jointly with the Endocrinological Section of the Royal Society of Medicine at the latter's premises at 1 Wimpole Street, London, W.1, on February 24, commencing at 10 a.m. Those wishing to attend, who are not members of either Society, should write to Prof. N. F. MacLagan, Westminster Medical School, 17 Horseferry Road, London, S.W.1, for further details.

AN advanced course on information work, under the general title of "Organization and Development of Information Services", will be held by Aslib during February 25-28, the first three days being held in the premises of the Department of Scientific and Industrial Research at Charles House, 5-11 Regent Street, S.W.1, and the last day in the Aslib headquarters at 4 Palace Gate, Kensington, London, W.8. The course will be mainly a series of lectures and is planned to be of maximum benefit to information workers with from three to five years experience in the field. The fee for the course is five guineas for members of Aslib and seven guineas for non-members. Further information can be obtained from the Director, Aslib, 4 Palace Gate, London, W.8.

THE Ministry of Education is arranging a short course in metallurgy for teachers from technical colleges, to be held in the County Technical College, Wednesbury, during July 14-24. The course, which will be directed by Mr. R. W. Blount, H.M. inspector, assisted by Mr. S. G. Lawrence and other H.M. inspectors, will deal with modern metallographic techniques, mechanical and thermal treatment, modern methods of analysis, and radiographic techniques, and those participating will take any two of these sections. The work will be mainly practical; but there will be certain main lectures which all will attend. The course is residential, and a charge of £13 will be made for the full board and lodging. The tuition will be free. Application forms (Form 106 TSC), which must be returned by May 15, and further information can be obtained from local education authorities.

THE Turkish National Institute of Bibliography issues regularly a "Bibliography of Articles Appearing in Turkish Periodicals" which lists, in French and Turkish, articles published during the months covered by successive parts. The entries are numbered serially and arranged according to the Universal Decimal Classification (to two places only); within each section titles are arranged alphabetically by author. A list of periodicals covered is given, together with an author index. Part 4 covers August-September 1952, and includes 3,753 entries.

ERRATA. In the article entitled "Steric Effects in the Electronic Spectra of Organic Compounds" (*Nature*, January 16, p. 119, col. 1, line 13), for " $\theta_1 = 90^\circ$ " read " $\theta_1 = 90^\circ$ "; line 22, for " $\theta_1 \approx 0^\circ$ " read " $\theta_1 \approx 0^\circ$ ".

SHORTAGE OF GRADUATE TEACHERS OF SCIENCE

AT a conference called by the Federation of British Industries in London, on January 14, to discuss the shortage of science teachers in schools, the president, Sir Harry Pilkington, said that the national interest demands that enough science teachers of quality, for all types of educational institution, shall teach and train students in the next few years, so that our scientific and industrial leadership of the world over the next generation may resist challenges. Sir Harry declared that "industry will pay the price of leadership; industry will invest in research, in development, in progress, in expansion and in science. Industry will try to face its obligations towards encouraging a greater national investment in education of this type".

The demand and supply of science teachers was examined by Sir Charles Morris, vice-chancellor of the University of Leeds, who said that in the 1920's and 1930's a really good graduate took a long time to get a public school or good grammar school job as a schoolmaster. In addition, in the 1920's and 1930's, schoolmastering still attracted many able young men from the universities as a worth-while and gentlemanly life. For various reasons this seems to be no longer the case. There is to-day an effective economic demand for these men in research of all kinds, for general posts in industry and for university, college and school teaching.

The peak of this demand has not been seen either for research or for general industry. For university and school teachers the peak may well be reached between 1955 and 1960.

Of the good academic men with fine personal qualities—of whom industry, research and the universities and schools all must have some—there are not enough to go round. Outside the universities and schools they are needed for fundamental and industrial research. A knowledge of the world and human nature is needed to provide the necessary flair and imagination for effective industrial research and for general posts in industry.

Sir Charles questioned whether the undergraduate body of scientists could be increased still further; it is not so easy as might be supposed. Most people agree that our present degree standards are pitched at about the right place, and that a policy of greatly increased admissions should not be advocated if it would lead to large numbers falling by the wayside at the end of the first year. The answer to the shortage of graduate teachers in science is that "we must make sure we are using well all the scientists we have in research and in industry and that we must somehow again make schoolmastering attractive to the young man of spirit, imagination and ambition".

How is this to be done? More and more people are coming to think that the benefits of salary and other differentials must go to good men who actually do the teaching as opposed to good organizers and administrators in the schools.

Dr. A. W. Barton, headmaster of the City of London School, stated that the problem is as much one of quality as of quantity. There are probably two hundred science posts in grammar schools vacant to-day, while both the academic and teaching ability of new science teachers is lower than it was in 1938; 10 per cent of the science teachers are either non-graduates or graduates in arts subjects. In the past

ten years, 975 science teachers have left the schools for industry or administration. The shortage of science teachers is now beginning to be felt outside the schools. Two hundred places in university engineering departments were unfilled last October. A hospital medical school in London had 30 per cent of its places vacant at the same time. The science examiners for two of the largest examining boards reported that the majority of last year's General Certificate of Education candidates at Advanced Level passed by learning the work by heart instead of understanding it.

Dr. Barton suggested some possible remedies for this situation which is developing disastrously. A high-level conference representative of all the interests who both train and use scientists should be called to try to secure their fairer distribution. Governing bodies and headmasters should readily give facilities for research to able science teachers, who express a wish to undertake it, probably at a neighbouring university or technical college. Governing bodies should also seriously consider appointing more science teachers to headships of schools.

Science graduates should be deferred from national service if they go into school teaching. The Scientific Civil Service might second some of its scientific officers for, say, five years to the Ministry of Education for employment as school teachers. The universities could foster a rare combination of qualities by instituting general honours courses of three subjects, one of which should be an arts subject, such as English or history, and the others science subjects.

The industrial point of view was put by Dr. P. Dunsheath, chairman of the Federation of British Industries Education Committee, who said that the whole vast field of technology rests on the teaching of fundamental science; "anything which saps at the roots which lie in school science will inevitably have a disastrous effect on the growth of the plant which proliferates through industry".

There is considerable evidence, culminating in the latest report of the Advisory Council on Scientific Policy, to show that Great Britain is already behind some of its important industrial competitors in the application of science. To meet this situation we need not only a restoration of our former standards of science teaching but also a considerable advance on those standards. For the successful operation of an industrial concern there must be mutual respect between the staffs employed in the different sections covering research, development and production, which is fortified by the knowledge that all concerned possess a common understanding of the scientific principles involved.

Industry is more and more alive to the fact that the boy who leaves school at fifteen or sixteen and depends on subsequent part-time education suffers a disadvantage in his climb to the more responsible positions in industry. More boys who now leave at sixteen should remain at the grammar school up to the sixth form, and then take a formal part-time industry-based course in the science and practice of their technology. Such recruits will be very much hampered if they arrive without a good basis of mathematics and science on which to build their technology. Moreover, the very fact of strengthening the sixth form by keeping more boys in touch with

academic life may influence a larger proportion to choose teaching as a vocation.

The question of the balance between teaching in arts and in science is of considerable importance. On the assumption that a good brain may be employed with equal profit in both scientific and arts subjects, the obvious solution is to deflect some of the arts students to science.

Many difficulties will be side-tracked if suggestions for bringing pressure on schools to change their outlook overnight, on local education authorities to increase their wages bill, or on teachers' unions to accept larger differentials, are avoided. All these may be desirable but, from a practical common-sense point of view, should be avoided at present because of their potential for delay. The course least prone to cause delay through vested interests would seem to be not to press for a change in the attitude of the schools but to give opportunities at university entrance for change-over to science and engineering and to provide suitable pre-entry courses for the purpose.

Although the problem is a complex one and there are many possible solutions, industry should not be asked to curtail its intake. Graduates are not being employed wastefully. The urgent need is a larger pool from which both teachers and industrial recruits can be drawn.

NORTH OF ENGLAND EDUCATION CONFERENCE

AT the North of England Education Conference, held at Morecambe on January 4, Mr. J. Chuter Ede gave the presidential address in which, reviewing the first ten years of the Education Act 1944, he said that the outstanding disappointment has been the failure to eliminate the competitive examination at the age of eleven. Inadequate effect has also been given to the principles, propounded in the White Paper which preceded the Act, of directing ability into the field where it would find its best realization, and of facilitating free interchange of pupils from one type of education to another. Other disappointments to Mr. Ede were the failure of all but nineteen of the 146 local authorities in England and Wales to submit the development plans based on the Act, which they had originally been required to do in six months, and the failure to correct the bias against craftsmanship and to do more than offer better opportunities for technical education at the secondary stage.

Mr. Ede's main plea was for unity among teachers, parents and authorities; but he offered a welcome warning against straining after uniformity and confusing this with unity. His remarks on technical education were taken up to some extent in a discussion on Tuesday morning which followed addresses by Mr. C. H. Wilson, principal of University College, Leicester, and Dr. P. F. R. Venables, principal of the Royal Technical College, Salford, on the place of the university and the technical college in higher technological education. Mr. Wilson began with a brief review of changes since the Barlow Committee in 1946 recommended the doubling of the output of university graduates in science and technology. While this was virtually accomplished by 1947, all official statements continued to demand a greater output; but it is important to distinguish between graduates in all branches of technology and graduates

in fundamental science, and between short-term and long-term requirements for either. On a short-term view, while the supply of scientists is adequate so far as industry is concerned, it is inadequate for schools; but on a long-term view the supply of scientists seems to be reasonably adequate for some time ahead, though the best judges consider that further expansion in technology is still needed.

Discussing the adequacy of the present official policy, Mr. Wilson suggested that there may still be scope for the development of new departments of technology in the newer universities. In the long run the future of technology at the universities will be determined by four factors: the ability to forecast national requirements for the different kinds of technologist; the growth in industry of a much more generous view of the place of development research; the supply by schools of students wishing to take technological degrees; and the development at universities of a consensus of opinion more congenial to the expansion of technological studies. Mr. Wilson said that he recognizes the difficulties and dangers to the academic health of the universities if any one faculty becomes out of balance, and he insisted that the universities have to face the larger questions of the place that technological studies should take in the life of the universities as a whole and the environment in which such studies are best conducted: technology is not necessarily best taught in the environment of a strongly materialistic philosophy.

Dr. Venables's paper was concerned more particularly with the technical colleges and with its contribution to technological education, which he distinguished carefully from technical education. Compared with the technical colleges, the universities are a small and relatively homogeneous group, and he argued that, in considering the contribution which the technical colleges could make to the expansion of higher technological education, quality not quantity of work is the essential criterion. Technological education he defined as for those who "maintain, manage and maximise industry", with special emphasis on the last two. Of the 422 institutions in England and Wales dealing to a greater or lesser degree with technical education, we need be concerned with no more than those 220, the principals of which qualify for membership of the Association of Principals of Technical Institutions. Further, analysis of the work of these institutions, including the courses they offer, enrolments, recognition by professional bodies, their conduct of research and postgraduate facilities and regional requirements, have convinced Dr. Venables that it is essential to concentrate on some twelve to fifteen only of these institutions. Full university conditions could not possibly be created even for 44 institutions, he said, let alone 220.

Dr. Venables argued realistically that the exhortations and provisions of the Ministry of Education Circular No. 98 on Governance, No. 94 on Research, and No. 255 on Recognized Courses of Advanced Technology do not suffice for the further development of major technical colleges. The increased grant of 75 per cent and the recognition associated with it should on no account be made to an institution the local authority of which has not granted it a properly constituted established governing body with full powers within an approved annual financial estimate. If the local authorities will not or cannot shoulder the financial responsibility involved in the present

grant system, the increased grant, he suggested, should be paid direct to the college and the balance recouped from one or more of the local education authorities concerned. Under such a scheme it would be possible to plan long-term developments—Dr. Venables hinted here at the quinquennial principle—academic freedom could be secured for the staff and residential hostels would be more readily forthcoming. Such major institutions would not be able to provide for all aspects of technological work, and closer links would be desirable with the industrial research associations, which have their own part to play. Nevertheless, he thought that, by increased full-time and sandwich courses, by post-advanced or postgraduate courses and by research in co-operation with industry and the research associations, and further development of management education and training, the fifteen major technical colleges he visualized could make a greatly enlarged and vital contribution to advanced technology in Great Britain.

Dr. Venables's suggestion to concentrate on twelve or fifteen major institutions was supported by Mr. Wilson, and in the discussion Mr. D. J. Williams assured him of the whole-hearted support of the Association of Principals of Technical Institutions. Mr. Williams also advocated a separate major technical colleges committee. There was some general support, too, for the view that the present grants system is weighted in favour of the universities and the arts rather than the technical colleges and the sciences. In his address during the afternoon session on education and the administrative and financial structure of local government, Prof. S. E. Finer, University College of North Staffordshire, presented evidence that, in spite of the steady increase in educational expenditure, local authorities are still not spending nearly as much as they could and should on education; but his address did not bear very closely on the special issues raised by Dr. Venables. Prof. Finer was convinced that we need as strong a local government as can be achieved consistently with national standards, and that it is absolutely impracticable to centralize the administration of the schools. A recalculation of 1958 costs in terms of 1953 prices and school population shows that there has been virtually no increase in that part of the cost of each child's education which falls on local authorities. The real rate burden is very small and has become very much lower than before the War. The case for additional grant seems to be exaggerated, and he thought that local authorities should continue to bear the burden, subject to a reform of the education grant formula to make it more distributive, and based on a rating revaluation in 1956 with provision for a more elastic policy of exemptions and allowances in hard cases.

The sessions on January 6 were concerned with education in other countries, in which Prof. J. A. Lauwerys, University of London Institute of Education, dealt with the situation in the United States, and Dr. G. B. Jeffery, director of the University of London Institute of Education, with the position in the African Colonies. Prof. Lauwerys emphasized the diversity, the size and newness of the American system. There is urgent need, he said, for the development of educational practices which will foster the steadiness of character, power of critical thinking, independence of judgment and the vision that America's new role of leadership demands of her citizens. Of the comprehensive school, he suggested

that the British would do well to study with care American experience and then try to avoid repeating the mistakes made by others: one cannot say that because comprehensive schools work in the United States they would work in Britain. On the whole, he thought that the American system is better geared than the British to the imperative requirements of an industrial and technological education, and this aspect also deserves close study. Prof. Lauwerys was also very impressed by the enormous strides which have been made during the past twenty years in developing the professional aspects of the study of education.

Dr. Jeffery's address outlined the rapid progress made by the newly created Gold Coast Government, and in the subsequent discussion Mr. A. L. Binns described the very different conditions in East Africa. Dr. Jeffery maintained that the new development plans of the African ministers to-day, which he believed are fundamentally right in the practical circumstances, in spite of foreseeable dangers, are possible only because of the efforts of missions and the Colonial Education Service over many generations. In East Africa, Mr. Binns thought that the only hope lies in a great reinforcement of the few teams of British technicians and teachers who are already raising moral and material standards in small areas, so that the effort may be sustained long enough for the development of character in African leaders when moral stamina has been undermined by the dissolution of their traditional culture. In this connexion, Mr. T. H. Baldwin urged that educationists should make it possible for British teachers to take short-term appointments in the Colonies without jeopardizing their prospects at home. On January 7, in a paper on the place of the three 'R's' in the curriculum, Miss M. V. Daniel, principal of Hereford County Training College, urged that language, whether in reading or writing, should be envisaged as the means of communicating ideas, and mathematics as an interpretation of the physical world.

AGRICULTURAL CROPS: QUALITY VERSUS QUANTITY

A MEETING of considerable significance to British agriculture was held at Cambridge during December 15 and 16, when the National Institute of Agricultural Botany held its second Crop Conference with the theme of "Varieties in Relation to Crop Production". More than five hundred Fellows of the Institute, including farmers, seed merchants, maltsters, brewers, millers and agricultural scientists, attended to hear papers and discuss the topical problems posed by a quickly changing national and international position in relation to the production of primary agricultural products. The bulging wheat silos of North America and the threats of surpluses of coarse grain from the U.S.S.R. and other countries, coupled with a 'free market' for grain in Great Britain, acted as a stimulating, if sobering, background to the proceedings, and it was a matter of great interest to see how the conference quickly settled down to discuss the economics of quality versus quantity in the production of two of the three crops being considered—barley, sugar beet and wheat.

Dr. H. Hunter introduced the subject of the barley crop, which occupied most of the first day, and

immediately the conference was plunged into the intricacies of crop ecology, the physiology of development, the action of fertilizers, and the relationship between yield and malting quality. Very soon, also, the vital impact of plant breeding on crop production became apparent, and the conflict of interests between the farmer and the brewer, when considering the best varieties to grow, asserted itself. It appeared, however, that the newer hybrid varieties are helping to bridge the gap, and the farmer may not have to decide whether to grow for quality or quantity, because it is hoped these hybrids may combine both attributes.

This last point was emphasized by two of the three following papers on barley, in which Mr. O. S. Elliott described the behaviour of the new varieties and unnamed hybrids in the official N.I.A.B. trials, and Commander A. Cory-Wright put the maltsters' and brewers' points of view in considering varietal behaviour and the processors' requirements. Elliott's account traced the changes in barley varieties available in Britain since the advent of Spratt-Archer and Plumage-Archer, which are still generally the maltsters' and brewers' first choice, through the introduction of the Danish variety Abed Kenia, with its stronger straw, earlier ripening and potentially higher yielding capacity of poorer quality grain, to the greatly increased number of foreign varieties of similar type but often of no greater value. The problem has been to try to find a variety combining the desirable grain characters of the Archer barleys with the improved field characters of the Danish and Scandinavian varieties, and considerable progress has been made in this direction with the newest hybrids between varieties representing these two classes of barley. Thus the Danish variety Carlsberg and the English variety Proctor may be considered as real advances in combining higher yield with good malting quality; while other English hybrids are due for release next year.

Cory-Wright's contribution emphasized the change in the varietal position, the dangers of increasing the number of varieties, and the impossibility of making an overall general analysis to cover individual brewer's requirements in spite of a widely accepted interpretation of what is good malting barley. It appeared, however, that growers' and processors' views on varieties were by no means irreconcilable, though a word of warning was given concerning certain new varieties like Herta and Rika with pretensions to being malting barleys but with greater suitability for stock feed. Considerable interest was shown in Dr. A. Eden's paper on the utilization of barley for feeding, and the place of this cereal in the animal's ration, in relation to the composition of the grain.

A different aspect of quality was discussed by Mr. S. T. Skelton, on the afternoon of the first day, when he dealt with the quality of seed stocks. Skelton described the two main aspects of this quality as the appearance—size, colour, and freedom from damage, disease and impurities—and the authenticity and purity of strain or variety. The use of better methods of handling seed with improved machinery, seed testing and seed dressing are important methods of achieving better physical qualities, while the development of seed growers' associations and inspection schemes have done much for authenticity and purity. The speaker acknowledged the very valuable part played by the National Institute of Agricultural Botany in this matter of improved seed

quality, which has done much to lay proper emphasis on the importance of the highest standards in seed stocks and of the choice of the best varieties.

The sugar beet crop came in for very different treatment from the barley crop, as might be expected from the difference in the agricultural economy, the processing, and the utilization of the two crops. Mr. O. S. Rose, who dealt with the crop in general, speculated on the reasons for the much increased production per acre of sugar beet, and discussed ways in which varieties could be improved to produce what he described as the ideal sugar beet variety of the future. The list of characters was formidable: regularly-shaped single-germ seeds of high germination capacity, easily processed for sowing in a precision drill; strongly growing plants resistant to disease, bolting and chemical sprays; roots of heavy weight and high sugar percentage with high juice purity; and large tops with neat crowns easily removed by machine. Rose dealt with the practical significance of these characters to the sugar beet and beet sugar industry in Great Britain, making especial reference to the importance of obtaining some control for virus yellows, and he gave warning, from the reported experiences on the Continent, against being optimistic of the benefits of the use of monogerm seed and polyploid varieties. Mr. L. A. Willey elaborated on some of the more important varietal characters already mentioned in describing the results of the N.I.A.B. trials, and made special reference to the importance of bolting resistance (in which the varieties Cambridge K.N.B. and Klein AA are best), and to the difference in the financial returns resulting from growing the beet as opposed to the poorest varieties. These two papers emphasized that in sugar beet there is no conflict of interests between grower and processor when it comes to the choice of variety.

The final session of the conference, on the second morning, was devoted to quality in wheat, four papers being given on this topic. Mr. L. Hector Read, in dealing with the economic aspects of wheat quality, referred to the millers' attitude to milling quality, and the quality of the flour in relation to the use to which it is to be put. Read emphasized the vital importance to the miller of these grain characters, and he pleaded for a greater understanding by the farmer of the manufacturers' needs when choosing the most suitable varieties to grow, because grain quality is such a strongly expressed varietal character. A similar argument was put forward by Mr. Sebert Humphries, who dealt with flour, bread and biscuits from the millers' point of view. Humphries gave an unequivocal account of the requirements of the miller, the characteristics of foreign and native wheats, and varietal differences on the mill. He asked for there to be a purpose in English wheat production and a due regard for the prestige of English wheats, while he made a strong case for the millers' discrimination in buying particular varieties. Mr. E. N. Greer pressed home the very real differences between wheat varieties in the type of flour they produce, and he also gave an account of tests for milling and baking qualities in the laboratory.

These three papers emphasized strongly the conflict of views between the requirements of the farmer on one hand and those of the processor and manufacturer on the other, except in certain types of wheat. Thus, the most acceptable varieties for the miller, who has to consider the manufacturer who

will use the flour, are mostly the 'quality' native varieties like Yeoman and Holdfast, while the farmer prefers the higher-yielding, stronger-straw varieties like Cappelle Desprez and Bersee, and the French-type Hybrid 46 bred in Britain. Occasionally the apparently conflicting requirements are reconciled, as in the variety Atle, while, as in barley, hope for further reconciliation was expressed in the characteristics of new hybrids. Mr. D. G. Bullard put the farmers' point of view, and questioned, as did most farmers present, whether the millers would be prepared to pay an adequate premium for grain quality to compensate for the lower yield of the varieties of accepted quality that are available.

As in the case of barley and sugar beet, the wheat problem was left for the plant breeder to resolve as best he can. The conference brought out most clearly the demand and necessity for further improvement in the varieties of the three crops. The scientific problems posed by such continuous improvement are varied, and the work of improving, testing and sifting the plant material is the foundation of a progressive crop husbandry.

The chairman on the first day of the Conference was Mr. Roland Dudley, and on the second day Mr. Samuel Taylor. Dr. G. D. H. Bell summed up the proceedings on both days. G. D. H. BELL

ANALOGUE AND DIGITAL COMPUTERS

PROCEEDINGS OF THE WESTERN COMPUTER CONFERENCE

THE proceedings of the 1953 Western Computer Conference, held during February 4-6 at Los Angeles, California, under the joint sponsorship of the Institution of Radio Engineers, the American Institute of Electrical Engineers and the Association for Computing Machinery, has now been published* and contains the full text of the technical papers and of the panel discussion, together with résumés of the four addresses, presented at the Conference. The papers were concerned with the application of computers to the handling of business data and to aircraft design and with recent developments in analogue and digital computing equipment. The subject of the discussion was "An Evaluation of Analog and Digital Computers", and the panel of four experts, under the chairmanship of Prof. G. D. McCann, of the California Institute of Technology, consisted of Dr. J. L. Barnes, a mathematician and engineer, Mr. F. Steele, vice-president of Digital Control Systems and an engineer, Dr. L. Ridenour, formerly a nuclear physicist and now vice-president of the International Telemeter Corporation, and Dr. A. W. Vance, an electronics engineer of the Radio Corporation of America.

The addresses were delivered by Dr. Simon Ramo, of the Hughes Aircraft Company, Dr. R. D. Huntoon, of the National Bureau of Standards, Dr. Lee A. DuBridge, president of the California Institute of Technology, and Dr. J. E. Hobeon, director of the Stanford Research Institute. Dr. Ramo dealt with the impact of computer development on the training

and utilization of engineers. He maintained that the development of computers is work which may soon be engaging the greatest number of engineers and scientists; specially trained graduates with a knowledge of the physical sciences (with emphasis on electronics), the workings of the human brain and business and industrial procedures in addition to government and labour regulations are required, and industry must particularly avoid large programmes until such capable technical experts are available. Dr. Huntoon discussed the factors influencing the effective use of computers and coined the word "psycho-numerosis" to describe the problem of matching computing machines to the needs of research workers. He suggested that "electronic brains", like human brains, in the process of evolution must adapt themselves to their environment in order to survive and prosper.

The complex problem of scientific man-power was the subject of Dr. DuBridge's address. He outlined the salient factors which affect the supply and demand of scientists and engineers and suggested measures to remedy the present inadequate supply. Finally, Dr. Hobeon, in an address entitled "New Equations for Management", reviewed the various new factors which the complexity of industrial operations have introduced and indicated how the facts produced by applied research may be properly presented to and utilized by the managements of industrial concerns.

The eighteen technical papers were presented in four sessions. The first and second sessions were devoted to applications of computers to commercial and to aircraft design problems, respectively. The third and fourth sessions dealt with more specific technical problems in the design and use of particular sections or types of computers and included papers on the 'Nordseck' computer; the new laboratory for three-dimensional guided missile simulation devised by the Reeves Instrument Corporation, New York; an improved cathode-ray tube storage system; ferroelectrics as a memory element for digital computers; and the solution of partial differential equations by difference methods using the electronic differential analyser.

METEOROLOGICAL OFFICE

ANNUAL REPORT FOR 1952-53

THE Meteorological Office has the task of meeting the civil and Service (except naval) requirements of Great Britain for meteorological information of all kinds and of improving by research its ability to meet those needs. A feature of the report of its work during the year April 1, 1952-March 31, 1953*, is that during this period the organization for the provision of weather forecasts and other information was extended. One example of this was the application to the east coast as a whole after January 31, 1953, of the system of special warnings of meteorological situations known to be associated with coastal flooding, which had been applied successfully to the River Thames in London for many years. Experiments in the transmission by facsimile equipment to selected out-stations of charts drawn at the Central Forecast Office were begun with the view of im-

purposes

we now have

PERICLASE

(MAGNESIUM OXIDE)

available in circular flats for windows

Periclase is a cubic crystal, having about the same coefficient of expansion as mild steel. Its transmission in the infra red is almost as high as rocksalt, but falls to about 50% at 9 microns. An important feature is that it can be used from very low temperatures up to about 1500° C.

proving the information and guidance available to outstation forecasters.

Inquiries for meteorological data and advice covered a wide range of industrial, agricultural and economic problems from the hatchability of hen's eggs to the effect of wind and low temperature on overhead cables and the irrigation of crops.

Much effort was again devoted to the study of meteorological data for high levels, and to methods of forecasting and making observations at these levels in connexion with the increasing demand for information for the navigation of jet aircraft. Charts of upper-air temperature and its variation were drawn on a world-wide scale, and a special study was begun of high-level winds over the tropics. Building began at the new radio-theodolite station at Crawley, Sussex, from which upper-air observations of hitherto unattained accuracy will be made.

In research into methods of forecasting, results of great theoretical interest were obtained from numerical calculations with electronic computing machines. In this work the machine is used to calculate the future pressure distribution from the present one by means of suitably modified forms of the equations of motion of the atmosphere. It is believed that this work is nearing the stage at which it will be of practical as well as theoretical value. Investigations were also made into the formation of anticyclones, and the detailed distribution of rainfall associated with depressions moving along selected tracks over and near the British Isles. Much research work was also carried out into questions of physical meteorology, such as the transfer of heat and humidity between the earth and the atmosphere (a subject of fundamental importance in pure meteorology as well as being very important in agriculture) and the formation of radiation fog. The Meteorological Research Flight carried out an extensive programme of research into problems of cloud physics and flying conditions.

Among the publications produced by the Office during the year may be mentioned a large "Climatological Atlas of the British Isles", "The Century of London Weather (1841/1949)", and a new edition of the "Observer's Handbook".

FOREST PRODUCTS RESEARCH LABORATORY, PRINCES RISBOROUGH REPORT FOR 1952

THE work of the Forest Products Research Laboratory, Princes Risborough, during the year 1952 is described in "Forest Products Research 1952", the report of the Forest Products Research Board and also of the director of the Laboratory, which was recently published*. During the year there has been little change in the nature and orientation of the Laboratory's work, but there has been a gratifying increase in research work both of the fundamental kind and also in technical projects of the broader sort which can lead to practical generalization.

The testing and evaluation of new tropical species, mainly from the British Colonies, continues to be the

* Department of Scientific and Industrial Research. Report of the Forest Products Research Board, with the Report of the Director of Forest Products for the year 1952. Pp. vi + 62 + 8 plates. (London: H.M.S.O., 1953.) 3s. net.

Laboratory's major project; but it is expected that the work which began last year on the assessment of home-grown soft-woods from various forest sites of the Forestry Commission will increase in proportion during the coming and successive years. These programmes of timber testing, together with advisory work, continue to occupy much of the available time of the staff. Seasoning and kiln-drying tests have been carried out on tropical hardwoods and home-grown soft-woods. Drying problems of interest are connected with the seasoning of birch for brush heads and the kiln-drying of East African pencil cedar (*Juniperus procera*) slats.

The "Lens Key to the Identification of Hardwoods" was published during the year, and a companion atlas of low-power photomicrographs is in course of preparation. With the help of the "Lens Key" and the atlas as a check, an investigator, even though he lacks access to a standard collection of timber, will be able to identify any of the four hundred timbers, both home-grown and exotic, dealt with in the "Key". The entomological branch of the Laboratory has been engaged on work connected with the excessive damage to imported tropical timbers by ambrosia beetles, the so-called pin-hole borers, so well known to the forest officer in India. The Laboratory has submitted to the Colonial Research Council a programme of research involving the appointment of three biologists as a West African Timber Insect Research Unit to be trained at the Laboratory; it is proposed that one should remain at the Laboratory, and the other two proceed to West Africa in due course, and this step has been approved by the Governments of Nigeria and the Gold Coast.

An unusual item which will interest many is a request by the Brewers' Society to have tests made to find a suitable substitute for oak for making beer barrels. History repeats itself: a century and a half ago the British Admiralty was searching the world for a substitute for oak for the construction of the wooden ships of the Navy, and it found teak; in the case of the beer barrel, the timber so far tested is, dahoma (*Piptadenia africana*), which has proved unsatisfactory. From beer the report goes to boats, tests having been undertaken as to the best way of making laminated bends for stern, hulls and frames. Work is also in progress on wood structure, timber mechanics and wood-working methods.

E. P. STEBBING

OVULATION AND PREGNANCY CORPORA LUTEA IN THE OVARIES OF THE HUMPBACK WHALE

By J. P. ROBINS

Marine Biological Laboratory, Division of Fisheries,
Commonwealth Scientific and Industrial Research
Organization, Cronulla, N.S.W.

IT has been fairly well established that a permanent record of the number of ovulations remains in the ovaries of whales¹, and this record can be used in the study of the age of the whale. However, to date, apart from attempts by Peters² and van Lennep³ to distinguish between the two types of corpora lutea (more properly corpora albicantia), one resulting from ovulation without subsequent fertilization and

Fig. 1

Fig. 2

Fig. 1. Recently formed corpus luteum of pregnancy showing gel-filled central cavity. From ovary of whale carrying 4-m. embryo.

Fig. 2. Regressed corpus luteum of pregnancy showing connective tissue-filled central cavity.

one resulting from pregnancy, no further methods of distinction appear in the literature. Peters assumed the differences in colour and texture of the corpora albicantia to be indications of "ovulation only" and "pregnancy", and made an estimate of the number of ovulations per year in blue and fin whales. Colour appears to be a function of age of the corpora themselves, for the smaller corpora albicantia (apparently the older ones for the most part) are as a rule a much darker coloured orange-brown than those formed later.

Van Lennep made a histological examination of the corpora lutea of pregnancy and regressing corpora lutea in blue and fin whales, and suggested two possible means of distinguishing between old corpora lutea of pregnancy and old corpora lutea of ovulation: (1) arrangement of trabeculae of connective tissue strands, (2) size of corpora lutea. Corpora lutea of pregnancy possess more connective tissue than corpora lutea of ovulation, and this may be reflected in the sizes of the degenerating corpora lutea. However, the overlap of sizes of the two types of regressing corpora lutea constitutes a problem.

During the winter seasons of 1952 and 1953, at the land-based whaling station at Tangalooma, Moreton Island, Queensland, Australia, many observations on the corpora lutea in the ovaries of the humpback whale (*Megaptera nodosa*) were made, and very particular notice was taken of functional corpora lutea both of early and late pregnancy, and also of the ovaries from females in the early and late stages of lactation. The remarkable feature observed was that in 100 per cent. of these cases (thirty-seven individuals of all types) each corpus in question possessed a central cavity, variable in size from individual to individual, but always quite noticeable, this cavity being filled with a gel substance or fibrinous clot or a slight serous fluid. The same close attention was paid to all other corpora lutea in the ovaries, and it was found that a variable proportion of corpora lutea did not possess this characteristic cavity or core.

The close examination of the corpora lutea demands correct orientation and sections no larger than 8 mm. in width.

Dempsey and Wislocki⁴ give a description of the ovaries of the humpback whale, and in their summary conclude "that the large size of the whale's corpus luteum imposes certain anatomical peculiarities and physiological limitations on its vascular supply. The luteal arterioles and capillaries

are apparently unusually long. The functional restrictions in consequence of the lengthening of these vessels make it impossible for the luteal tissue ever to fill the entire cavity of the luteal body. These limitations result also in nearly complete avascularity of the centre of the corpus luteum associated with excessive fibrosis and hyalinization". Although van Lennep⁵ does not agree with this supposition, his statement on size comparisons does not necessarily invalidate it.

In all observations made at Tangalooma, the size of a 'corpus luteum of ovulation' did not exceed 88 mm., while those of late pregnancy and early lactation measured 100-130 mm.

All functional corpora lutea of early pregnancy possessed a central cavity filled with gel substance; but there were also cases where corpora lutea containing gel were not accompanied by an embryo in the very early stages of development in the uterus, although these could have been missed as the Fallopian tubes were not irrigated to discover whether fertilization had taken place. However, the early anatomical changes in the recently formed corpus are not quite clear as yet; but the sequence generally appears to be as follows for (a) 'ovulation' only, (b) 'pregnancy'.

(a) In 'ovulation only', the follicle ruptures and the egg passes to the Fallopian tube. The collapse of the follicle is followed by a rapid proliferation of the luteal cells with subsequent deposition of gel or hyaline substance (due to lag in growth of blood vessels behind the growth of luteal tissue). If pregnancy does not intervene, the gland attains a size of 80 mm., up to which size it appears possible for the blood vessels to supply sufficient blood without further hyaline degeneration into the centre, the luteal cells continuing to grow inward without much further increase in diameter of the corpus (up to a maximum of 88 mm. only), the further growth of luteal cells forcing the central gel to migrate into the deep crypts between the folds of luteal tissue. Apparently this gel, assisted by the adventitial cells

Fig. 3

Fig. 4

Fig. 3. Recently formed corpus luteum, considered to be a corpus luteum of 'ovulation only'. Note absence of a central cavity. No embryo in uterus.

Fig. 4. Regressed corpus luteum. Considered to be a corpus luteum of 'ovulation only'.

ally visible layers and corresponding to a network of cellulose chains making an angle of some 80° with each other. Complete understanding of such a structure is obviously impossible without an investigation of that of the *individual layers*—to decide whether even the finest layer has a structure similar to that of the whole wall. . . . The developmental study which we have made does just this, and it shows, moreover, how the first and the successive layers are laid down.

Preston and Astbury still seem to insist upon their original evidence for one set of cellulose lamellae in which the fibrils consist of a set of meridians. The arduous technique which leads to this conclusion was apparently carried out only upon one vesicle. Even so, the angles at which the chain directions crossed varied quite considerably at different parts of the wall and it seems that it would require more strict evidence to postulate a preferred direction as absolute as the system of meridians requires—evidence that should relate to more than one vesicle. Also, the evidence for the supposed poles seems not so convincing now as it might earlier have seemed to be. The areas in question gave an X-ray diagram which suggests disorder and random orientation, and this effect, through the whole thickness of the wall, might have arisen in other ways than the one suggested.

It is clear that the results of X-ray examination and of electron microscope studies of the same specimen should be compatible. It is granted that the X-ray method, and prominently so in the hands of Preston and Astbury, has yielded most valuable results. It is, however, still based on observations that have to be made over a relatively short length, which have to be extended over the wall surface as a whole, and it requires interpretations that are obviously complicated when dealing with a system composed of many successive layers each with its own fibrillar direction. Obviously what one does with the electron microscope is not to photograph one field but many such. The degree of integration which is obtained by the X-ray method, because it summarizes events over a given length, is obtained at least in part with the electron microscope by the taking of many pictures on many specimens and deciding from a very large number what is a typical condition and sequence of events. The electron microscope has, however, the great advantage that in each such field investigated the picture revealed has a degree of definition and precision that is not inherent in the X-ray method, which must average in each observation over a considerable area and many layers. Whereas in the electron microscope the several layers can be seen in sharp focus and the strand directions clearly discerned, the X-ray method only reveals this after interpretations that require to be made, and these, as is now evident, are subject to some uncertainty. For example, Preston and Astbury now suggest that the apparent prevalence of two layers in their work instead of three could be accounted for if one of these failed to show properly because two of them are more crystalline than the other. This is just the kind of problem that makes studies of this sort difficult by the X-ray method. The electron microscope seems to lead more directly to precision.

We can agree with Profs. Preston and Astbury that this, like any other problem of biology, requires further study. Our purpose here is to suggest that

understanding must comprehend how the structure of an organism grows and develops and, in achieving this, there is no substitute for the use in the investigation of the living material under such conditions that the changes that occur during growth can be observed. The application of this point of view to the problem of the *Valonia* wall has produced knowledge that did not arise from Preston's and Astbury's earlier work. This does not mean that the earlier results are to be rejected. It does mean, however, that knowledge grows by new observations, by the application of other techniques and by the different approaches that may be adopted by other investigators. It would be surprising and somewhat depressing, indeed, if sixteen years after the first major examination of the *Valonia* wall, made primarily upon a single vesicle, that this did not prove to be so.

In our view, the really challenging problems that these organisms still present are the following. What is the enzymatic machinery which permits the naked protoplasmic surface of the aplanospore so rapidly to build up cellulose in the manner that has now been described? What is the carbohydrate substrate that is utilized? What are the forces that control the first shift from randomly oriented fibrils to such strongly oriented parallel directions? Having once achieved order in the first direction, what induces the organism to lay down its fibrils in the successive directions which seem to be required? Even though there may be room for some difference of opinion concerning the minutiae of the structure of the mature wall, these great problems still present their challenge and the way seems now open for them to be attacked.

ZONE ELECTROPHORESIS OF
MUSCLE EXTRACTS SEPARATED
OF PHOSPHORUS
CATIONS
PERCENTAGE

Fig. 1. Detection of rabbit muscle constituents by ultra-violet fluorescence after electro-phoretic separation on filter paper.

0.7 μ l. (upper half) and 1.0 μ l. (lower half) of neutralized muscle extract deposited at $\pm$. Spots marked $\times$ are starting points corrected for electro-osmosis. 165 min. electrophoresis at 25° C. and 10 V./cm. in sodium succinate buffer - sodium chloride of pH 5.6 and μ 0.45

1, phosphocreatine (as creatinine); 2 and 3, positions assigned to adenosine tri- and diphosphate, respectively; 4, adenosine monophosphate; 5, oxidized diphosphopyridine nucleotide; 6, creatine (as creatinine); 7, ascorbic acid and carnitine. Distance between centres of spots 1 and 5 corresponds to 90 mm.

Photograph taken with two 'Mineralight' lamps (2 hr. exposure) and two 'Philora' lamps (5 min. exposure), all approximately 40 cm. from the filter paper. $F = 23$; Ilford Rapid Panchromatic plate, shielded from ultra-violet rays by Wratten G filter and 15-mm. mirror glass plate

The usual procedure in the present experiments was briefly as follows: Cold perchloric acid extracts of fresh skeletal and cardiac muscle were neutralized and concentrated to a volume corresponding to 40 gm. muscle per ml. For electrophoresis, 0.1-2 μ l. was placed on or near the centre axis of an 8-cm. wide sheet of Munktell 20 filter paper; up to 250 μ l. was used per 100 c.c. of Whatman cellulose powder saturated with buffer medium and packed tightly into an elongated 'Perspex' frame. The electrophoreses were carried out at potential gradients of 10 volts per cm. (filter paper) or about 3½ volts per cm. (cellulose powder) in the apparatus and with the precautions described by Kunkel and Tiselius¹, the filter paper being held tightly between two silicone-treated glass plates. The current ranged from 2 to 50 m.amp. Cooling and temperature control, when desired, were achieved by letting the lower of the two glass plates surrounding the filter paper rest on a large metal block, partly immersed in a water-bath of the proper temperature and by covering the upper glass plate with a metal trough filled with water of the same temperature. The duration of the electrophoresis runs on filter paper was ½-3 hr.; the cellulose powder experiments were run over-night. At the end of the runs the paper sheets, serving as supporting medium, and strips of paper pressed briefly against the surface of the cellulose powder packs, were dried in an air-stream at room temperature and inspected in ultra-violet light of around 254 m μ .

(Mineralight lamps, V. Products, Inc.). This revealed the fluorescent spots and their positions. The fluorescent spots were then photographed with two 'Philora' lamps at 254 m μ .

of skeletal muscle is furnished by the photograph reproduced in Fig. 1. This experiment was carried out at an estimated temperature of 25° C. in 0.175 *M* succinate buffer of pH 5.6, brought to ionic strength 0.45, by addition of sodium chloride. As can be seen from the photograph, satisfactory resolution of several of the ions studied was achieved. It was important at the pH employed and at the relatively high ionic strength and the resulting high current (28-30 m.amp.) to prevent heating in the paper in order to avoid decomposition of the highly acid-labile phosphocreatine. As is to be expected,

this compound moves toward the anode at a high speed (spot 1 in the photograph). In addition to showing up as a dark spot in ultra-violet light, it could be revealed on the heated filter paper as creatinine by spraying with alkaline picrate², and as phosphate by treatment with acid molybdate reagent and hydrogen sulphide³. Further identification and quantitative analysis were afforded, following elution from the paper and treatment intended to convert phosphocreatine into creatinine, by the characteristic ultra-violet absorption curves and maxima of the latter compound⁴. Quantitative determination as the phosphate was not feasible because of insufficient separation at the pH's employed from free orthophosphate. The paper-chromatographic behaviour⁵ of the eluate from the area occupied by spot 1 on the unheated paper served as a further check on the identity of the eluted substance with phosphocreatine.

The spots at positions 2, 3 and 4 in Fig. 1 have been assigned to adenosine triphosphate, adenosine diphosphate, and adenosine monophosphate, respectively, on the basis of evidence provided by the ultra-violet absorption spectra of the eluates, by tests for acid-labile phosphate groups, and by comparison with authentic samples with respect to speed of migration in the electric field at various hydrogen-ion concentrations. Due mainly to the choice of a not very favourable pH and to the large amount of adenosine triphosphate present, this compound did not separate from the diphosphate in the experiment shown. As has been reported by other authors^{6,10}, separation of the adenosine phosphates by electrophoresis is best undertaken at pH 3.7-4. Hypoxanthine derivatives were not seen in significant quantities in extracts of fresh skeletal and cardiac muscle, but were found to prevail in cardiac muscle excised ½-1 hr. after death of the animal (calf). Similar observations were made during analyses of extracts of brain and of the conductive tissue of the heart. The acid-extractable nucleotide content of the latter tissue was found only about one-fourth that of ventricular

the substance responsible for spot 5 in Fig. 1. It was identified as oxidized diphosphopyridine nucleotide. A small amount of this substance was prepared from the corresponding zone in the cellulose powder extract isolated exhibited an absorption maximum in ultra-violet at 260 m μ . Electro-

an anion having about the size of a dinucleotide and carrying an average net charge not higher than unity. Its speed of migration toward the anode in this pH range was therefore compared with that of authentic diphosphopyridine nucleotide, and was found to be the same. Like the latter compound, the zone 5 substance was split by standing in 0.5 *N* sodium hydroxide for 15 hr. at 37° C. chiefly into adenosine-5-phosphate and a moiety which, judging from its electrophoretic properties, is probably nicotinamide mononucleotide. Contrary to what might be expected from the report of Schlenk, von Euler and co-workers¹¹, nicotinamide and its riboside are not major products of this alkali treatment. Appearance of an absorption maximum at 340 mμ on reduction with sodium hydrosulphite^{12,13} of the material eluted from zone 5 left little doubt as to the presence of diphosphopyridine nucleotide. Significant amounts of other substances containing nitrogen, ribose, or phosphate were not present in the eluate. In unfractionated perchloric acid extracts of calf heart muscle that has been contracting partly anaerobically for about one minute, oxidized diphosphopyridine nucleotide accounts, at pH 2, for 5-8 per cent of the absorption at 260 mμ, which is the absorption maximum of adenine and nicotinamide. In fresh rabbit skeletal muscle the corresponding percentage is lower.

Spot 6 in Fig. 1 was found to be due to creatinine formed from creatine by heating the filter paper, as evidenced by positive colour reactions on spraying the unheated and heated papers with α-naphthol-diacetyl¹⁴ and alkaline picrate¹⁵ reagents, respectively. The eluate from the unheated paper behaved like a solution of authentic creatine with respect to *R_F* values¹⁶ and ultra-violet absorption^{17,18}, both before and after treatment designed to transform creatine into creatinine. Another test for creatinine given by spot 6 and also by spot 1, after electrophoresis in 0.05 *M* potassium phosphate buffer of pH 5.9, was the appearance of a yellowish-green fluorescence following application of butyric acid at high temperatures¹⁹. For some unknown reason, creatine, present in and added to the muscle extracts migrated with a greater velocity towards the cathode than creatine applied separately, which at pH 5.6 is almost stationary.

Anserine and carnosine were identified as the components of fluorescent spot 7. The fluorescent material moved in the electric field with the same velocity as the authentic peptides. Carnosine was revealed on the paper as an intense red stain after spraying with alkaline diazobenzenesulphonate²⁰, while spraying with ninhydrin followed by heating produced a green coloration²¹. The eluate from the spot gave the same *R_F* values on the paper chromatogram as the authentic peptides^{19,22}, and yielded an ultra-violet absorption curve characteristic of imidazole compounds^{21,23}. (Using a Hilger 'Uvispek' photoelectric spectrophotometer we find the absorption maximum of L(+)-carnosine to lie at a somewhat lower wave-length than was reported by de Gouveia *et al.*²³, namely, at 212 mμ ($\epsilon = 6,600$), both at pH 3 and 11.) Because carnosine and anserine differ only slightly with respect to size, shape and ionization (see ref. 23), electrophoresis offers little chance for separating these compounds from each other. However, it makes possible their rapid separation from the bulk of the other muscle constituents.

The unmarked spots in Fig. 1 have not yet been identified. The bright fluorescent spot situated close behind phosphocreatine gave a positive reaction with the aniline hydrogen phthalate reagent²⁴, which suggests that the rapidly moving anion may be a phosphorylated sugar. Spraying of the filter paper with ninhydrin revealed, in addition to carnosine and anserine, a number of other ninhydrin-positive compounds present in appreciable amounts. Two of these, for which the heart of new-born animals is a good source, appear to be phosphorylated. This phase of the present work is not yet completed.

In some experiments, such as that represented in Fig. 1, requirements for determination of mobilities on paper were, in the main, fulfilled. Thus, evaporation of water from the liquid medium was held at a minimum, electro-osmosis was estimated, and other factors tending to disturb migration in the electric field, particularly adsorption of the ions under study on the paper, were taken into consideration. Making allowance for the electro-osmotic flow and for a 15-25 per cent retardation in the movement of the nucleotides, due to adsorption, and applying the correction factor of Kunkel and Tiselius¹ for non-linearity of the path of ionic migration through Munktell 20 filter paper, the following mobilities of some of the ions studied are obtained, at pH 5.6, ionic strength 0.45 and 25° C.: phosphocreatine, -20.6×10^{-8} ; carnosine, 8.8×10^{-8} ; oxidized diphosphopyridine nucleotide, -6.4×10^{-8} ; adenosine monophosphate, -11.5×10^{-8} ; and adenosine triphosphate, -17.7×10^{-8} cm.² volt⁻¹ sec.⁻¹. Mobility values for adenosine mono- and triphosphates calculated from filter paper experiments undertaken at ionic strength 0.1 and 0° C. were found to agree quite well with values¹⁹ obtained under these conditions in free electrophoresis.

This work was undertaken during tenure of a Life Insurance Medical Research Fellowship. I wish to express my sincere thanks to Prof. A. Tiselius and to Dr. O. Snellman for their hospitality and interest. I am also indebted to Mr. S. Jersted for performing the electrophoresis runs in packed cellulose powder, to Prof. H. M. Kalckar for a sample of diphosphopyridine nucleotide, to Dr. A. Deutsch for a sample of anserine nitrate, and to Dr. M. Ottesen for a sample of carnosine. [Aug. 25.]

Internal Structure in Virus Particles

PREVIOUS electron microscopic studies of chick embryo chorioallantoic membranes infected with herpes simplex virus have revealed that the development of virus in susceptible (ectodermal) cells apparently begins in the nucleus and is completed in the cytoplasm¹. In the nucleus, the smallest particles considered to be virus measured 40–60 mμ in diameter and the largest did not exceed 130 mμ in diameter. Larger particles, some having a maximum linear dimension of 250 mμ, were seen in the cytoplasm or in extracellular locations. These observations were made on thin sections of tissue from which the methyl methacrylate had been dissolved by amyl acetate.

More recently, particles thought to be transected herpes simplex virus have been seen in ultra-thin sections of infected chorioallantoic membrane from which the embedding substance was not removed. Within the nuclei of cells the virus appeared to consist of a central, spherical body (40–60 mμ in diameter) of varying density, often surrounded by a single membrane (70–130 mμ in diameter), as illustrated in Fig. 1. Within the cytoplasm the particles were generally larger than 130 mμ in diameter and usually possessed a double membrane, as illustrated in Fig. 2. The membranes were separated from each other and from the central body by zones of lesser density. It thus seems reasonable to infer that herpes simplex virus has a definitive inner structure which may be related to its cycle of development within the cell. In this connexion, attention may be directed to the hypothesis of viral structure advanced by Pollard from purely theoretical considerations². The observations reported here tend to support his concept of a central body and an inner zone or membrane in the mature or complete viral particle.

This work was supported by grants from the Lillia Babbitt Hyde Foundation and the Lederle Laboratories Division, American Cyanamid Company.

Since submitting the above communication, which deals only with the virus of herpes simplex, an internal structure has been observed in both vaccinia and influenza virus. In vaccinia virus a body strikingly similar to a cell nucleus may be seen; the structure of influenza virus more closely resembles that of herpes simplex virus. These observations are being extended.

A Method for the Rapid Differentiation of Certain Non-pathogenic, Asporogenous Bacilli

It is the experience of most microbiologists that the differentiation of the non-pathogenic, asporogenous, non-pigmented rods is of considerable difficulty. These bacilli form an appreciable part of the air-soil-water microflora and, in materials from marine environments, such as fish, in which our interests are focused, they comprise 60–80 per cent of the total number of species isolated¹. The main difficulty is that, by the usual tests, most of these micro-organisms appear to be biochemically inert, and the classification, based on a series of negative characters, is not very determinative. The types of organism we have in mind are usually classified among the Pseudomonadaceae, Achromobacteriaceae and Bacteriaceae of Bergey² and Prévot³. In Bergey, the Pseudomonadaceae comprises, among others, the genera *Pseudomonas*, *Vibrio* and *Spirilla*, and the Achromobacteriaceae the genera *Achromobacter* and *Flavobacterium*. In Prévot, however, the *Vibrios* are removed from the Pseudomonadaceae and form a genus of the Spirillales, while the *Achromobacter* and *Flavobacterium* become genera of the Pseudomonadaceae. Comparison with a recent Russian determinative system⁴ shows even wider divergences, the Achromobacteriaceae disappearing altogether, being grouped as *Bacterium* spp. under the Bacteriaceae.

A good example of the present difficulties is the differentiation between the *Pseudomonas* and *Vibrio* spp. According to Bergey, the former are more or less straight rods, usually forming a diffusible pigment, whereas the latter are usually curved rods with no pigment production. In practice, this

differentiation is not easy, and is never satisfactory, more particularly as many *Pseudomonas* spp. lose the property of forming pigment on continued subculture and some never appear to have possessed it.

In some work done here in 1949 with the help of Dr. N. Reynolds, now of the Ministry of Agriculture and Fisheries Laboratory, Conway, on the effect of certain antibiotics on a variety of bacteria isolated from marine fish, it was noted that the types provisionally classified as *Pseudomonas* spp. could be divided into two clearly differentiated groups. Further work, which has included the use of certain vibriostatic agents^{1,2}, has now resulted in a scheme for the differentiation of the *Pseudomonadaceae* of Bergey, which it is thought might be of interest to others in this field. The method employs the normal sensitivity test for antibiotics, using antibiotic tablets, or in the case of the vibriostatic agent, a saturated aqueous solution in an assay cup.

All pigment-producing pseudomonads so far studied from a variety of sources, even although they may have lost the power of pigment production on subsequent subculturing, have been found to be insensitive to the antibiotics and the vibriostatic agent at the concentrations listed in Table 1. On

the other hand, all the *Vibrios* so far tested react to both terramycin and the vibriostatic agent. Indeed, many of the types from fish, provisionally classified as *Pseudomonas* spp., now appear by this test to be *Vibrios*. The remaining group of *Pseudomonas* spp., which grow somewhat slowly and never form pigment under any conditions so far tested, can also be distinguished by their sensitivity to terramycin (Table 1). Admittedly the total number of strains tested has been relatively small (about two hundred) and future work may well reveal many exceptions. It is considered, however, that such a scheme may well surmount the difficulties of identifying non-pigmented strains of *Pseudomonas* spp. from clinical material, mentioned recently by Gaby and Free³.

An extension of this work to the other groups of asporogenous non-pigmented rods has resulted in a sensitivity scheme which, together with morphology, reaction to Gram's stain, etc., can quickly differentiate between the main groups of *Pseudomonas*, *Achromobacter* and *Bacterium* (Table 2 and Fig. 1). This provisional scheme has been found particularly useful in the preliminary screening and grouping of several hundred primary isolates from fresh fish⁴, and other workers faced with similar problems may find that some such scheme could be adapted to their own field. Further work with other species both from

marine and terrestrial sources is proceeding. A full account will be published elsewhere.

We are indebted to Dr. H. O. J. Collier, Pharmacology Department, Allen and Hanburys, Ltd., Ware, Herts, for the gift of a generous sample of the vibriostatic agent.

Effect of Experimental Tuberculosis on the Distribution of Alkaline Phosphatase in the Adrenal Cortex of the Guinea Pig

It has been reported earlier that stressor agents like epinephrine¹ and adrenocorticotrophic hormone² cause a loss of alkaline phosphatase activity from the adrenal cortex. Administration of serum gonadotrophin to epinephrine-treated pigeons partially prevents this enzymatic loss³. The present communication records an attempt to determine whether a comparable reduction in alkaline phosphatase activity occurs in the adrenal cortex in response to a bacterial infection stress.

Twelve male guinea pigs weighing on an average 520 gm. were used in this work. Six animals were injected subcutaneously with a human strain of tubercle bacilli (H37RV) of tested virulence, in a dosage of 1 mgm. (wet weight of the inoculum emulsified in 1 c.c. of 0.9 per cent physiological saline solution) per animal. The inoculated animals were killed after eight weeks and post-mortem findings revealed extensive tubercular lesions with caseation in the lungs, liver, spleen and the lymphatic glands. The control animals were injected with 1 c.c. of physiological saline solution in a similar manner and were killed along with the infected animals. Prior to killing, all the control animals were tested with tuberculin and were found to give a negative reaction. The adrenals were carefully dissected out and processed according to the technique of Gomori⁴ for the demonstration of alkaline phosphatase.

In the control guinea pigs, the glomerular zone exhibits intense phosphatase activity. The entire area appears as a dark band and the contours of the parenchymal cells are totally obscured by granular deposits of cobalt sulphide (Fig. 1). In the outer fasciculate the nucleus of the parenchymal cells reacts in a strong positive manner; but the distribution of the enzyme is somewhat diffuse in the cytoplasm. The endothelium of the vascular sinusoids of this area, however, shows pronounced phosphatase activity. In the inner fasciculate and the reticularis, on the other hand, the parenchymal cells are virtually devoid of enzyme activity. This is also the case with the endothelium of the vascular sinusoids of these areas.

Macroscopically, the adrenals of the infected guinea pigs are considerably enlarged in size; this could be ascribed mainly to the hypertrophy of the cellular parenchyma of the fasciculate zone. The glomerulosa shows no histological response to tuber-

cular infection, and no pathological changes could be detected in any part of the cortex. Cytochemically, a pronounced loss of phosphatase activity is clearly evident upon microscopical examination. In the outer fasciculate the parenchymal cells react only in a faint manner, and similarly the endothelium of the vascular sinusoids of this area. The inner fasciculate and the reticularis are totally devoid of phosphatase activity. Considerable amounts of the enzyme, however, are retained in the glomerular zone (Fig. 2).

It is therefore evident that the above findings agree with previous work¹⁻³ and indicate that in a bacterial infection stress also there is marked loss of phosphatase activity from the adrenal cortex. The enzymatic loss is probably associated with the rapid metabolism and subsequent decline in critical lipids known to occur during stress conditions. It is interesting that plasma alkaline phosphatase activity in rats shows a comparable reduction in response to adrenocorticotrophic hormone stress⁴.

I wish to thank Dr. B. Mukerji for the interest he has taken in this study, and Dr. S. K. Gupta for valuable help.

Choline Deficiency in the Guinea Pig

THE brief report by Reid¹ of the "production of clear-cut deficiencies of . . . choline . . ." in the guinea pig is of considerable interest, as Handler² had previously failed to produce fatty livers in guinea pigs maintained on a hypolipotropic diet and had correlated this failure with the low choline oxidase content of guinea pig liver³. In view of this discrepancy, we present histochemical evidence here of the centrilobular deposition of fat in the livers of guinea pigs fed a hypolipotropic diet. Such accumulation of fat is characteristic of choline deficiency in the rat⁴.

Twenty male guinea pigs of about 550 gm. weight were divided into two similar groups and fed the diet shown in the accompanying table, choline being omitted from the ration of one group. The diets were mixed with some ground osho (Purina Rabbit Chow Checkers, obtained from the Ralston Purina Co., Ltd., Woodstock, Ontario) for the first twelve days, the proportion of the synthetic diet being gradually increased to 100 per cent. The group receiving the choline-supplemented diet was pair-fed on a twice-weekly basis against the deficient group. All animals received oral supplements of ascorbic acid every three or four days. They were maintained on these regimens for as long as 160 days. Some were sacrificed at intervals before this time so that there were only three survivors in the deficient group and six receiving the supplemented diet. The average gains in weight of the longest-surviving animals in these groups were only 112 and 162 gm. respectively.

Frozen sections of the livers were studied with oil red O, sudan black B and Nile blue sulphate. The histochemical findings are illustrated by Figs. 1 and 2. Although a few fat droplets occurred in the

Photomicrographs of sections through the adrenal cortex of (1) a normal guinea pig; (2) guinea pig infected with tuberculosis. Note reduction of staining reaction. $\times 80$

COMPOSITION OF THE DIET

	Per cent		Per cent
Gelatin	1.0	Liver powder	1.0
Oseam	2.0	Salt mixture†	4.0
a-Soya protein	5.0	Vitamin mixture‡	2.0
Extracted peanut meal	12.0	Cystine	0.15
Cereogram	7.0	Choline chloride*	0.20
Starch*	10.25	Corn oil	1.0
Dextrin	10.0	Beef fat	4.0
Glucose	20.0	Cod liver oil concentrate	0.015
Sucrose	20.0	α -Tocopherol acetate	0.010

* In the preparation of the choline-deficient diet, the choline chloride was replaced by an additional 0.5 per cent starch.

† The salt mixture contained the following per kgm.: calcium carbonate, 117 gm.; calcium acid phosphate, 885 gm.; dipotassium phosphate, 775 gm.; magnesium sulphate, 100 gm.; sodium chloride, 150 gm.; iron citrate, 50 gm.; manganese sulphate, 1.945 gm.; zinc sulphate, 0.350 gm.; copper sulphate, 0.400 gm.; potassium iodide, 0.005 gm.; sodium fluoride, 0.005 gm.; potassium alum, 0.040 gm.; cobalt chloride, 0.005 gm.; sodium silicate, 0.20 gm.; and sodium arsenite, 0.010 gm.

‡ The vitamin mixture contained the following per kgm.: biotin, 20 mgm.; thiamine hydrochloride, 500 mgm.; riboflavin, 250 mgm.; pyridoxine hydrochloride, 200 mgm.; calcium pantothenate, 1,000 mgm.; nicotinic acid, 1,000 mgm.; folic acid, 50 mgm.; 2-methyl-1,4-naphthoquinone, 100 mgm.; p-aminobenzoic acid, 10.0 gm.; and sucrose, 987 gm.

§ The cod liver oil concentrate (Ayerst, McKenna and Harrison, Ltd., Montreal, Que.) contained 200,000 I.U. vitamin A and 50,000 I.U. vitamin D per gm.

periportal cells in both groups, only in the choline-deficient animals were there many fine droplets in the centrilobular cells. The liver lipids were not estimated chemically.

That more severe signs of choline deficiency were not observed may have been due to the choice of guinea pigs older than those used by Reid¹ and to their very limited growth during the experimental period. The small gain in weight may be of significance in two respects. First, it would result in a decreased demand for methionine for protein synthesis, labile methyl groups being conserved in this way². Secondly, it suggests that the relatively low caloric intake might have produced a pseudo-lipotrophic effect³. Such considerations would appear to apply also to Handler's experiments. We would suggest that the difficulty of producing fatty livers

in guinea pigs by maintenance on a hypolipotropic diet should not be attributed to the lack of hepatic choline oxidase until it is clear that the difficulty is not simply that of securing a high caloric intake in guinea pigs on an artificial diet.

This investigation was supported in part by a research grant from the National Research Council, Canada.

Steroid Requirements of Housefly Larvae

It has been known for some time that with very few exceptions¹ insects require only the unsaponifiable, not the saponifiable, fractions of lipids. According to Hobeon, for example, the larvae of *Lucilia sericata* require cholesterol as an extraneous growth factor, and they are capable of synthesizing neutral fat from a lipid-free peptone diet under sterile conditions. Since then, many insects have been found to require a sterol (zoosterol, phytosterol or mycoosterol) as growth factor.

This communication describes some preliminary experiments on the specificity of steroids as growth-factors for the housefly (*Musca vicina* Macq.). The experiments, which form part of a more comprehensive study², were carried out with larvae on a diet composed of wheat bran and water (1:1), which had been inoculated with a standard bacterial flora (*E. coli*, *Sarcina lutea*, *Lactobacilli* and *Bacillus subtilis*). All experiments were carried out at $35 \pm 0.5^\circ$, and the weight increase (daily) and pupation time of the larvae were recorded. It has, of course, been shown³ that the above bacteria do not synthesize the lipids required by the larvae. Fig. 1 (p. 212) shows that a lipid-free diet, that is, a diet extracted exhaustively with chloroform (curve a), retards the development of the larvae (both in time and in weight) and practically prevents pupation. Cholesterol or sitosterol (curve b) in a quantity of 0.17 per cent (the normal sterol content of the wheat bran used) restores the growth curve to normal: a maximum weight of 22–23 mgm. per larva is reached after four days, and between the fourth and fifth day, 100 per cent

Fig. 1. Liver of guinea pig pair-fed choline-supplemented diet. A few periportal but no centrilobular cells contain fat droplets. $\times 40$

Frozen sections of formalin-fixed tissues. Oil red O, hematoxylin and light green

Fig. 1. Growth curves of the pre-adult stages of *Musca vicina* reared on various diets: (a) chloroform-extracted wheat bran; (b) extracted wheat bran, after addition of 0.17 per cent cholesterol or sitosterol; (c) extracted wheat bran, after addition of 0.17 per cent Δ^4 -cholesten-3-one; (d) extracted or non-extracted wheat bran, after addition of 0.17 per cent cholestan-3-one or cholestan-3-ol; (e) control diet.

pupation takes place, followed by the normal weight decrease. Δ^4 -Cholesten-3-one (curve c) has practically the same effect as cholesterol, when applied in a concentration of 0.17 per cent. Cholesterol (and Δ^4 -cholesten-3-one) acts, therefore, both as growth and pupation factor; it is essential for pupation.

Very surprising was the effect of cholestan-3-one (curve d). It permitted the growth of the larvae to a weight of about 7 mgm. on the fourth day; then the weight decreased, and on the sixth day the larvae died. Exactly the same curve was obtained when unextracted wheat bran was used as culture medium and 0.17 per cent of cholestan-3-one was added. Thus the saturated ketone acts as an antimetabolite; its effect appears to be irreversible. Obviously, the larvae of *Musca vicina* are incapable of dehydrogenating the saturated sterol ring system. This is supported by the observation that cholestan-3-ol has the same effect as cholestan-3-one.

The experiments are being continued with other steroid derivatives and simpler analogous compounds.

Synthesis of Ribose in Animal Tissues

RECENTLY, we described experiments showing the synthesis of deoxyribose in guinea pig liver extracts by the coupling of a triose with acetaldehyde¹. The substitution of glyceraldehyde for acetaldehyde as the 2-carbon compound might be expected to lead to the synthesis of ribose instead of its deoxy-derivative, and this has now been shown to occur.

The preparation of the tissues and the general analytical techniques were as previously described¹. Liver extract was incubated with glyceraldehyde (final concentration 0.08 M) together with fructose-1,6-diphosphate (0.02 M) as a source of triose; iodoacetate (0.008 M) was added to prevent triose breakdown. After incubation, the sugar-phosphate fraction was separated by precipitation with barium acetate and ethanol. Barium was removed from this fraction, and the barium-free solution acted upon by alkaline phosphatase. Analysis by paper chromatography then gave clear evidence of the presence of the two keto-pentoses, xylulose and ribulose, which must initially have been present as phosphate derivatives. These sugars showed all the reactions of authentic samples on the chromatogram, and on elution gave absorption curves with the orcinol reagent showing typical peaks at 670 m μ and 540 m μ . The cysteine-carbazole reaction (see Cohen²) was also used in identifying the sugars.

By removing samples from the incubate at different intervals, it could be shown that the formation of xylulose phosphate preceded that of ribulose phosphate (Fig. 1). It seems likely that this reaction, brought about by liver extracts, is the same as that already demonstrated in aldolase preparations of pea seeds by Forrest, Hough and Jones³, who, starting with the same substrates, were able to identify xylulose and a little ribulose as products of their reaction. Though the synthesis of ribulose phosphate by a mechanism other than the oxidative decarboxylation of hexose derivatives has not previously been reported in animal tissues, our findings agree with those of Glock⁴, who has recently shown the accumulation of a ketopentose-1-phosphate (presumed to be xylulose-1-phosphate) when triosephosphate and glyceraldehyde were incubated in the presence of liver fractions. There are also some earlier reports of similar experiments in which pentose was found but not characterized⁵.

An additional finding in our experiments was the formation of a ribose phosphate in some of the incubates. Since this pentose, like the two keto-

Fig. 1. Development of ketopentoses by the method of Bryson and Mitchell⁶. A, ribulose standard (green spot); B, 30 min. incubation—xylulose only; C, 1 hr. incubation—xylulose and ribulose; D, 2 hr. incubation—xylulose and ribulose; E, control (no glyceraldehyde)—no ketopentose; F, xylulose standard (blue-grey spot).

pentoses, did not appear unless both hexosediphosphate and glyceraldehyde were present as substrates, and then only after the formation of xylulose, it is most unlikely that it was the product of the oxidative decarboxylation of hexose compounds. The evidence suggests that the synthesis was the result of the coupling of dihydroxyacetone phosphate and glyceraldehyde to give xylulose-1-phosphate, and the successive conversion of this compound to a ribulose phosphate and thence to ribose phosphate.

Since liver tissue has been shown to contain a pentose-phosphate isomerase⁶, the synthesis of ribose in a system already giving rise to ribulose phosphate might be expected; the conversion is established as an essential step in the formation of ribose by the oxidative decarboxylation of hexose derivatives⁷. The mechanism of the formation of ribulose phosphate from xylulose phosphate, involving an inversion at carbon-3, is less readily explained, though it could be regarded as bearing some analogy to the conversion of glucose to galactose for which a specific waldenase enzyme system exists⁸, or to the interconversion of ribulose and arabinose, for which an enediol intermediate has been suggested⁹. It seems clear, however, from these experiments that, contrary to earlier views, ribose-like deoxy-ribose can be synthesized in animal tissues by a condensation of 2-carbon and 3-carbon compounds.

Prosthetic Group of Cytochrome a_2

CYTOCHROME a_2 , which is found in certain bacteria, for example, *Aerobacter aerogenes* and *Azotobacter*, has particular interest as it may play the part of a cytochrome oxidase in these organisms. The main absorption band of this cytochrome in the visible part of the spectrum is in the red region: reduced, 630 m μ ; oxidized, 645 m μ ; carbon monoxide complex, 635 m μ . Spectroscopic similarities to some ferroporphorobides¹ as well as to certain bile pigment iron complexes² have been observed.

We have now obtained haemin a_2 free from protohaemin. *A. aerogenes* was cultivated under conditions of vigorous aeration by which the cytochrome a_2 content is increased³. The haemins were extracted with acid-acetone and, after removal of phospholipids, the green haemin a_2 was separated from protohaemin by precipitation of the latter by benzene.

The acid haematin (in glacial acetic acid) has a principal maximum of absorption at 603–5 m μ and a smaller maximum, of one-fifth the height, at 750 m μ . The alkaline haematin shows a maximum

at 662–64 m μ , the haem at 618 m μ , and the pyridine haemochromogen at 613–15 m μ . Cyanide forms a compound with haematin a_2 in alkaline solution, causing the disappearance of the band at 662 m μ ; on reduction with dithionite, a band appears at 618 m μ . Carbon monoxide also reacts with haem a_2 ; the band has the same position as that of the haem, but is of greater intensity.

By removal of the iron from the haemin by means of the ferrous acetate-hydrochloric acid or the ferrous formate method a chlorin-like pigment is obtained. Re-introduction of the iron restores the spectrum of haematin a_2 . In neutral solvents this chlorin has two principal maxima of absorption. In dioxane they are 654 m μ and 503 m μ . Three much weaker bands are found at 597, 572 and 533 m μ . The Soret band has a maximum at 405 m μ . In 10 per cent hydrochloric acid a maximum is shown at 630 m μ . The position of these maxima differs from those of the chlorins, pheophorbides or rhodins, for which data are recorded in the literature.

The 'HCl number' of the free chlorin is close to that of protoporphyrin; but the R_F value of the methyl ester of the chlorin when run on paper chromatograms using the kerosene-chloroform or kerosene-propanol solvents of Chu *et al.*⁴ is markedly less than that of protoporphyrin ester.

Lipoid material remains even in the purest preparations. It is possible that, like porphyrin a^1 , the prosthetic group of cytochrome a_2 possesses a lipophilic side-chain.

When the chlorin and the haematin were treated with hydroxylamine by the methods of Lemberg and Falk⁵, there was no shift in the position of the band at 652 m μ of the chlorin in pyridine or the band at 615 m μ of the pyridine haemochromogen. Thus it is unlikely that the side-chains of the prosthetic group possess a formyl or carbonyl group.

The evidence for assuming that this haemin and chlorin were derived from cytochrome a_2 is as follows. The intensity of the acid haematin band at 603 m μ , or of the chlorin band at 652 m μ in acetone, was proportional to that of the cytochrome a_2 band. *Azotobacter vinelandii*, *Escherichia coli* and *Proteus vulgaris*, all known to contain cytochrome a_2 , yielded this haemin and chlorin. When the bacteria were grown anaerobically, neither cytochrome a_2 , haemin a_2 , nor chlorin was obtained. Some organisms such as *Bacillus mycoides*, *Bacillus subtilis* and *Pseudomonas aeruginosa* developed relatively small amounts of cytochrome a_2 when grown in liquid medium with vigorous aeration, and correspondingly gave small amounts of this haemin and chlorin.

We therefore conclude that the isolated haem and chlorin are the prosthetic group and iron-free prosthetic group, respectively, of cytochrome a_2 .

This work has been carried out with a grant from the National Health and Medical Research Council of Australia.

Cysteine and Phosphoserine containing Peptide Sequences of Ovalbumin

To investigate whether certain amino-acid sequences, for example, cysteinylglycine¹, occur with greater than chance frequency in different proteins^{2,3}, a method has been devised for the isolation and identification of cysteine containing sequences, and for peptide sequences containing O-phosphoserine, a compound with which at least one of the two phosphorus residues in ovalbumin⁴ has now been identified. 2-gm. portions of four times crystallized, performic acid oxidized⁵ ovalbumin were precipitated and washed with trichloroacetic acid, hydrolysed with 40 ml. of 11 N hydrochloric acid for 3-7 days at 37°, and hydrochloric acid removed *in vacuo* below 25°. A strongly acid peptide fraction was separated from the hydrolysate by washing through a 4 cm. x 10 cm. 'Dowex 50' (H⁺ form) column with water, and the effluent was dried *in vacuo*, neutralized in small volume, and applied to a 1 cm. x 50 cm. 'Dowex 2' column (pH 3, Cl⁻ form). Slow elution with 400 ml. hydrochloric acid rising continuously from 0.001 to 0.05 N provided fractions containing only one to three peptides, separable by one-dimensional paper chromatography. Composition and N-terminal amino-acid of each peptide were determined by paper chromatography of sealed-capillary hydrolysates (11 N hydrochloric acid, at 110°) of aliquots, with and without treatment with dinitrofluorobenzene⁶.

Essentially all the strongly acid components of a seven-day hydrolysate have been identified (Table 1); they include eleven dipeptides of cysteic acid (theoretical maximum fourteen, assuming no duplications⁷). Because of its acidity and composition (cf. Perlmann⁸), chromatograms of the one peptide lacking cysteic acid, aspartyl (glutamic acid, serine), were sprayed with the reagent of Hanes *et al.*⁹, after marking ninhydrin-positive spots. The presence of phosphorus was readily demonstrated.

Table 1. PEPTIDES IDENTIFIED IN A SEVEN-DAY HYDROLYSATE OF OVALBUMIN

In order of elution from 'Dowex-2' columns:

cysteyl (alanine, valine)	threonylcysteic acid	cysteic acid
cysteylalanine	valylcysteic acid*	aspartyl (glutamic acid, serine)*
cysteylglutamine	cysteylglutamic acid*	cysteylphenylalanine
cysteylvaline	phenylalanyl cysteic acid	aspartylcysteic acid
cysteylcysteic acid	glutamylcysteic acid*	

* Identified in relatively small amounts in only one hydrolysate.

When performic acid oxidation was omitted, most of the peptides passing through the cation exchanger contained phosphorus, and were then easily purified because of their small number. Free phosphoserine was identified by comparison of its *R_F* and that of its dinitrophenyl derivative in three solvents with corresponding authentic samples (gift of Dr. William H. Summerson), and traces of it were usually also found in hydrolysates of its peptides (Table 2). Since only two dipeptides of phosphoserine were identified, it is likely, though not certain, that they belong to the same sequence, aspartylphosphoserine-alanine (aspartylserinephosphoserine and phosphoserinealanine would not be expected to survive the partial hydrolysis), and that isoleucine and glutamic acid are joined to this sequence, but not directly to phosphoserine. Analyses¹⁰ of an acid hydrolysate of each dipeptide (Table 2) suggest equimolar ratios, considering serine destruction, under these conditions.

Table 2. PHOSPHORUS-CONTAINING COMPONENTS FROM OVALBUMIN

	Amounts in micromoles isolated from 1 gm. protein			
	Phosphorus Before hydrolysis	Phosphorus After hydrolysis	Serine	Aspartic acid
Phosphoserine	0	0.27	0.25	0.32
Aspartylphosphoserine	0.03	1.03	0.58	1.18
Phosphoserinealanine				
Aspartyl (glutamic acid, phosphoserine)*				
Aspartyl (alanine, glutamic acid, isoleucine, phosphoserine)				

* Identified in relatively small amounts in only one hydrolysate.

Since C-terminal serine peptides have not previously been found in acid hydrolysates¹¹, the isolation of aspartylphosphoserine from 3- (though not 6-) day hydrochloric acid hydrolysates supports the view that the acid lability of serine-amino peptide bonds is due to N to O acyl migration⁸. The successful application of these methods to ribonuclease¹², and particularly the association of aspartic acid, glutamic acid and isoleucine¹³, and alanine¹⁴, with phosphoserine in casein, encourage a search for systematically recurring sequences in proteins. This, as well as studies on the role of glutathione as precursor of the cysteinylglycine of ovalbumin, will be reported elsewhere.

Coproporphyrin Formation in Yeast

In recent articles in *Nature*, Keilin¹ has described the occurrence of haemoglobin, in very low concentration, in certain strains of bakers' yeast, and Keilin and Thiersch² have likewise demonstrated the presence of haemoglobin in the mycelia of the moulds *Neurospora crassa* and *Penicillium notatum*. In the latter investigation, free protohaem was also found, especially in fragments of mycelium undergoing autolysis, following their projection from the aerated nutrient on to the walls of the containing vessel. The free haem in the moulds appeared to originate from intracellular haemoglobin and from some components of cytochrome by an enzymic degradation which accom-

panied the autolysis of the mycelium. In old mycelia, the free hem itself was further degraded with liberation of iron and the formation of free porphyrin. These important findings are particularly relevant to the study of porphyrin formation in autolysing yeast.

Experiments with top-fermentation brewers' yeast have shown considerable increase in yield of porphyrin following treatment with solid ammonium carbonate and glucose¹, to yield coproporphyrin isomers I and III in varying proportion, but with traces only of proto- and deuterio-porphyrins. Coproporphyrin in the medium was itself undergoing change, and apparently accumulated owing to the relative rates of formation and removal being out of phase⁴. Exogenous added cytochrome and catalase were destroyed in the yeast preparation, but did not augment the yield of coproporphyrin. From observations on the effects of various chemical agents, it was concluded that coproporphyrin probably did not arise from by-products of fermentation, but possibly as a result of rapid proliferation of the yeast cells, using ammonium carbonate as a ready source of carbon and nitrogen.

Further studies have been made on the relationship of coproporphyrin concentration to other aspects of yeast metabolism, such as respiration, fermentation and cell division. To facilitate sampling, the yeast was diluted with distilled water after it had been subjected to ammonium carbonate-glucose treatment. The addition of water was responsible for much lowered yield of porphyrin.

The results now obtained do not support the earlier view⁴ that the yeast cells in the ammonium carbonate-glucose preparation are growing rapidly. An early fall in the total cell count was observed, which may have arisen from the combined effects of restricted oxygen supply to a medium densely packed with cells⁵, and of plasmolysis of many cells, causing them to resemble cellular debris, overlooked in counting. The majority of cells enumerated at 21 hr. were granular in appearance. Rates of respiration and fermentation also showed a decline, indicating that the predominating changes in the yeast were autolytic in character. Also, coproporphyrin concentration was independent of the rates of cell division, respiration and fermentation.

The evidence points to formation of coproporphyrin in these yeast preparations, not through excessive synthesis in actively dividing cells, but rather by catabolism of preformed intracellular hemoproteins in damaged or dead cells, as described in mould mycelium³. Although earlier work⁴ has shown no conversion of added exogenous cytochrome *c*, catalase or (unpublished observations) human hemoglobin, this does not exclude such endogenous hem derivatives as possible sources of porphyrin. Moreover, the frequent occurrence of free hem in extracts, and the conversion of proto- to coproporphyrin in yeast, lend support to this hypothesis. Addition of protoporphyrin 9 to yeast alone resulted in increased formation of coproporphyrin as shown in Table 1.

Table 1. COPROPORPHYRIN IN YEAST FOLLOWING ADDITION OF PROTOPORPHYRIN 9

1 mgm. protoporphyrin added to 100 gm. top-fermentation brewers' yeast, and coproporphyrin and residual protoporphyrin measured after 24 hr.

Coproporphyrin present (μgm.)		Protoporphyrin recovered (μgm.)
control	100 gm. yeast + protoporphyrin	
102	418	72

The increased yield (316 μgm.) of coproporphyrin associated with the disappearance of 928 μgm. protoporphyrin 9 suggests that yeast is able to convert protoporphyrin 9 into coproporphyrin, and the latter could arise from a protohem derivative.

The events leading to porphyrin formation may be conceived as follows. Cytological damage liberates intracellular hemoproteins from structures inside the yeast cell, and thus renders these pigments accessible to the action of proteolytic enzymes. Attack upon and digestion of the protein moiety of the hemoprotein liberates the hem group, and from this porphyrin is readily derived.

The mode of action of ammonium carbonate and glucose, by which regular, marked facilitation of porphyrin production is achieved, remains for study. Glycine, urea, acetamide, glutamic acid, *d*-glucosamine and asparagine were all without effect. It is clear, however, that porphyrin appears in yeast through processes quite dissimilar from those liberating it during hemopoiesis in man, in which coproporphyrin forms part of the biosynthetic pathway from glycine to hemoglobin.

Human Visual Purple and Absolute Threshold

I HAVE just read the interesting communication by Drs. Crescitelli and Dartnall on human visual purple (rhodopsin)¹. The last paragraph of that article may give rise to the impression that new evidence has been brought forward, as a result of which the work of Hecht, Shlaer and Pirenne² on the minimum number of light quanta necessary for vision might have to be considerably revised. Such an impression would, I think, be mistaken. Crescitelli and Dartnall were able to repeat and confirm König's³ measurement, made in 1894, of the optical density of the rhodopsin extracted from a human retina. On such a basis König calculated the percentage *p* of the light incident on the human retina which should be absorbed by the rhodopsin contained in the living rods, and found *p* = 4 per cent for $\lambda = 0.51 \mu$. Crescitelli and Dartnall now find *p* = 3.5 per cent. König's result was quoted and taken fully into account in the above paper by Hecht *et al.* Crescitelli and Dartnall's work, however valuable in other respects, affects but little the outcome of the discussion.

The small difference found by Crescitelli and Dartnall between frog and human rhodopsin is irrelevant with regard to the higher value, *p* = 20 per cent, which Hecht *et al.* chose as a basis for their calculations. It would have tended to increase, rather than to decrease, this value. This cannot be discussed here, but a more important fact is that the 20 per cent value was purposely chosen as an upper limit by Hecht *et al.* Such a limit was required because, when that paper was written, the main

point of interest was to establish that the minimum number n of quanta actually involved in a visual act must be very small, namely, of the order of 10 or less, instead of about 50 as had usually been believed hitherto⁴. Hecht *et al.* wrote: "From the comparison it is apparent that the 5 per cent maximum absorption curve [of rhodopsin] describes the points [of the corrected sensitivity curve] quite well, but that the 20 per cent curve is definitely excluded because its absorption on both sides is just too high. . . . However, to be quite safe, we may take 20 per cent as the upper limit for the absorption of 510 m μ by the visual purple in the human retina after complete dark adaptation". Now, Crescitelli and Dartnall write: "Their [Hecht *et al.*] figure of 20 per cent absorption by the visual pigment was based on an indirect calculation in which it was implied that the scotopic pigments of frog and man were identical". This is, I think, somewhat misleading.

Crescitelli and Dartnall do not mention the dichroism of the retinal rods which Schmidt⁵ observed in 1938. Such dichroism seems likely also to exist in man. If so, even assuming that no losses of rhodopsin occurred in the extraction made by König and by Crescitelli and Dartnall, their values for p may be too low. If losses occurred, the true value of p must be higher still. Another source of uncertainty with regard to the retinal threshold n relates to the transmission of light by the pre-retinal eye media⁶. The problem as a whole is too complicated to be discussed here, but a word may perhaps be added in connexion with Crescitelli and Dartnall's estimate of n , which they suggest is equal to "1-3 quanta approximately". Various indirect methods prove that n is greater than 1; there is general agreement on this point among workers in the field⁷; and there are also strong reasons⁸ for believing that n is greater than 2.

Occurrence of Dieldrin-resistance in Wild *Musca domestica* L. in England

THE ability of insects to develop a resistance to an insecticide is now widely acknowledged. It has also been shown that, where resistance to a specific insecticide exists, the toxicity of related compounds can be tolerated also, though probably to a lesser extent. This communication reports the occurrence of a high degree of resistance to dieldrin (an insecticidal product containing not less than 85 per cent of 1,2,3,4,10,10-hexachloro-6,7-epoxy-1,4,4a,5,6,7,8a-octahydro-1,4,5,8-dimethanonaphthalene, and not more than 15 per cent of insecticidally active related compounds), in a wild strain of *Musca domestica* L. which had not been exposed to this insecticide prior to this investigation.

Trials carried out during the past summer to assess the value of dieldrin for the control of the common housefly, *Musca domestica* L., on a refuse tip in Hertfordshire, proved unsuccessful. During the past four years insecticides containing DDT and gamma BHC have been applied to control flies on this refuse tip. The development of a housefly population resistant to DDT and BHC was therefore suspected. The American workers Bruce and Decker¹ have demonstrated by controlled laboratory experiments that BHC-resistant flies show some tolerance to dieldrin. If this wild strain of houseflies was resistant to BHC, the failure of these trials with dieldrin could be explained. The resistance of the wild housefly population to DDT, gamma BHC and dieldrin was therefore investigated.

Houseflies were collected from the refuse tip and reared in the laboratory under standard conditions without further contact with insecticide. The progeny was tested, concurrently with a normal laboratory culture, against technical DDT (80 per cent *p,p'* isomer), BHC (99 per cent gamma isomer) and technical dieldrin (which contains 90-95 per cent dieldrin), formulated as oil sprays. A modification of the direct spray technique described by Kearns and Marsh² was used, the insecticides being sprayed at concentrations calculated to give approximately 10-90 per cent mortality in 24 hr. (Table 1). All tests were carried out at 80° F. and 50 per cent relative humidity.

Comparison of the strains for resistance was made on the L.D. 50 (concentration of insecticide required to give 50 per cent mortality) estimated from log-probit regression lines. The resistance of the laboratory strain was taken as 1.

Pyrethrins	Laboratory	0.1	43	—	—
	Wild	0.1	37	—	—

It was not possible to test each insecticide against the same generation of flies from the wild strain, owing to insufficient numbers being available. Third generation flies were tested for resistance to DDT and dieldrin, and fourth generation flies for resistance to gamma BHC. A check test with dieldrin against the fourth generation of flies indicated that there was no difference in resistance between the third and fourth generations.

Each strain was also tested against the official test insecticide (0.1 per cent w/v pyrethrins), which is the standard prepared by the Chemical Specialties Manufacturers Association, 110 East 42 Street, New York, U.S.A., and used in many countries; 'normal' strains give 30-55 per cent mortality when sprayed with it.

The wild strain of houseflies was found to be 19 times more resistant to DDT, 53 times more resistant to gamma BHC and 266 times more resistant to dieldrin, than the normal laboratory culture (Table 1). Bearing in mind that the wild strain was resistant to gamma BHC, some resistance to dieldrin was anticipated, but the concentration of dieldrin tolerated was surprisingly high in comparison with the normal strain. There appeared to be little difference in resistance to pyrethrins.

The magnitude of dieldrin-resistance shown by the wild housefly population cannot be readily explained, as the insecticide had not been used for fly control on this particular refuse tip before these trials were undertaken.

Thermo-chemical Seed Treatment

NEWHOOK¹, using the technique of Baylis², reported that a hot-water steep of 10 min. at 52.8° C. controlled seed-borne pasmo (*Sphaerella linorum* Wollenw.) in seed-lines of linen-flax (*Linum usitatissimum* L.). Watson *et al.*³ have recently reported the use of carbon tetrachloride as a suitable material in place of water for heat treatment of peas and beans. It has been shown by them that germination of peas and beans was not affected by a 60-min. steep at 75° C. Heat transfer into the seeds was demonstrated, but very little carbon tetrachloride was absorbed.

Experiments have been carried out to determine the effect of a carbon tetrachloride steep on germination and control of seed-borne pasmo in linseed. Thirty-six temperature-time combinations were studied, ranging from 5 min. to 30 min. with 5 min. variations, and from 50° C. to 75° C. with 5 deg. temperature differences.

Two varieties, namely, Golden Viking and Koto, were treated. 10-gm. lots of seed were steeped in a carbon tetrachloride bath maintained at the different temperature-levels by a Towers thermostatic control unit. Seed was germinated in Petri dishes on moist filter pads in an incubator at 22° C. for seven days. Seed was examined for viability of *S. linorum* (a) by the technique of Loughnane *et al.*⁴, followed by removal of spores to Van Teigham cells and incubation at 22° C. for 24 hr.; preparations were stained with cotton-blue lacto-phenol, and examined for the presence of germ-tubes; (b) by plating surface disinfectant seeds on 'Bacto-prune' agar in Petri dishes and incubating at 22° C. for six days.

No mucilaginous sludge developed in the course of treatment, and no carbon tetrachloride appeared to be absorbed. Results of germination counts are presented in the accompanying table. Analysis of these results showed significant depression of germination only at 70° and 75° C. for 30 min. with Golden Viking and 20 min. with Koto. These treatments also markedly reduced vigour of the seedlings, their development being two to three days slower than those of untreated seed.

In the technique used for determining spore germination, no germ-tubes were observed after treatment for 20 min. at 65°, 70°, 75° C. or for 30 min. at 80° C. In the plate tests, no cultures were obtained from seed treated for 15 min. at 70° or 75° C., 20 min. at 65° C. or 30 min. at 60° C. Untreated seed samples yielded 14 per cent infected seed (Fig. 1).

A similar experiment, using linseed infected with browning (*Polyspora lini* Laff.) and the plating technique, has also been carried out. No cultures were obtained from seed treated for 15 min. at 70° C. or 20 min. at 65° C.

From these preliminary experiments it would appear that complete control of two seed-borne diseases of linseed can be obtained by a carbon tetrachloride steep at times and temperatures which do not affect germination.

The use of carbon tetrachloride in place of water as a material for heat-treatment of linseed has two technical advantages over the latter: first, the safety limits with respect to germination are wider; secondly, no artificial drying of seed is necessary. On the other hand, a specially designed steep for elimination of fumes and recovery of carbon tetrachloride given off as a vapour during the treat-

An Antagonist of the Sterility Hormone Rutin in the Green Alga *Chlamydomonas* *eugametos*: Ombuoside=7,4'-Dimethyl- rutin

RUTIN (= quercetin-3-rutinoside) prevents the copulation of male and female gametes in *Chlamydomonas eugametos*¹. Its effect is very specific. Checking more than forty flavonols, it was found that only rutin induces sterility. The sugar at carbon atom 3 (rutinose) seems to be important, as quercitrin (= quercetin-3-rhamnoside) does not influence fertility.

In 1935 a strain was obtained which could not be made to copulate². Filtrates of these *agametos* cells, like rutin, prevented the copulation of *eugametos* gametes. Thus *agametos* cells produce and secrete a sterility hormone. This hormone could be isolated from cells of a certain *agametos* mutant. It was identified as rutin³ (I).

Three enzyme systems dependent on genes are responsible for rutin formation in *agametos* cells: (1) the formation of *l*-rhamnose (gene *rha*⁺), (2) the formation of rutinose from *l*-rhamnose and *d*-glucose (gene *runo*⁺), (3) the formation of rutin from quercetin and rutinose (gene *ru*⁺). *Agametos* has *rha*⁺*runo*⁺*ru*⁺, *eugametos* has *rha*⁺*runo*⁺*ru*⁺. Quercetin could be isolated from cells of a *ru*⁰ *agametos* mutant⁴, suggesting that the biosynthesis of rutin follows the sequence given above.

However, *agametos* cells become able to copulate when the cells are kept in the dark for three days. Then the cells are practically free of rutin. They lose their ability to copulate after a period of illumination of 15–20 min. During the short period of copulation, it is possible to cross *agametos* with *eugametos*. The effect of rutin is not yet clear. It is evident that the formation or the secretion of gamones which induce the last phase of the copulation is disturbed.

We have now been able to examine ombuoside (II), a glycoside that is a 7,4'-dimethyl-rutin, which has been obtained from the leaves of the ombu (*Phytolacca dioica*, L.), where it accompanies rutin⁵. The results of the experiments are: (1) ombuoside (10^{-4} gm./ml.) shows no influence on the copulation of *eugametos* gametes; (2) *agametos* cells obtain the ability to copulate in solutions containing 10^{-4} to 10^{-7} gm./ml. ombuoside; (3) *eugametos* gametes made sterile by rutin (10^{-4} gm./ml.) begin to copulate again after adding ombuoside (10^{-4} gm./ml.); (4) *eugametos* gametes continue to copulate in solutions containing ten times more ombuoside than rutin.

We conclude from these results that ombuoside is able to compensate the rutin effect.

We also tested 7,4'-dimethyl-quercetin or ombuin, the aglycone of ombuoside. It has no influence on *eugametos* gametes. However, we found that ombuin compensates the sterility of *agametos* cells. This effect may indicate that *agametos* cells can form ombuoside enzymatically from ombuin.

The specificity of 7,4'-dimethyl-quercetin was demonstrated by examination of ten other methyl derivatives of quercetin (for which we thank Dr. I. Loew, Max Planck-Institut fuer Medizinische Forschung, Heidelberg), namely: 7-, 5-, 3-, 3', 7,3-, 3,5,3', 3,7,3', 5,7,3', 5,3',4', and 7,3',4'-methyl quercetins were without any effect on *agametos* cells. These results show that 7,4'-dimethyl-quercetin (ombuin) and 7,4'-dimethyl-rutin (ombuoside) have a special importance in this antagonism with rutin.

Distribution of Radio-Frequency Brightness across the Solar Disk and the Derivation of a Model Corona

DETERMINATIONS of the distribution of radio-frequency brightness across the solar disk have been made by Stanier¹ at a wave-length of 80 cm. and by Machin² at a wave-length of 3.7 metres. A series of similar observations has been carried out by one of us³ at wave-lengths of 1.4, 3.7 and 7.9 metres during the period July 1951–July 1952. In this communication we describe the results of an attempt to derive a model of the corona which is consistent with these observations⁴.

made about N or T ; instead, an attempt was made to derive these quantities directly from the radio observations. The model which was found to fit the observations most closely was given by:

$$N = 1.6 \times 10^8 R^{-1} \text{ cm.}^{-3}$$

$$T = 2 \times 10^6 R^{-2} \text{ deg. K.}$$

over the range $R = 1.2 R_s$ to $3.0 R_s$, where R_s is the radius of the photosphere.

This distribution of electron density agrees well with that of Allen for small values of R , but for R greater than $2R_s$, the density decreases more slowly outwards.

The extent to which the new model can account for the observations is shown in the graphs. It is

Distribution of radio brightness across the solar disk at three wave-lengths. The distance from the centre of the disk is given in terms of the radius of the photosphere (R_s).

—, Experimental curves; limits within which the experimental curves are believed to fall; ---, theoretical curves

The experiment showed that the contours of constant radio brightness were roughly elliptical in form and varied slightly from day to day. As a first approximation for the purposes of theoretical interpretation, they were replaced by constant circles. The average radial distributions which were used in this way to represent the experimental results are shown as continuous lines in the accompanying graphs. The uncertainty of the experimental results is indicated by the dotted lines, which show the limits within which the distributions are believed to fall. The limits are predominantly caused by an uncertainty in the absolute scale of brightness (because small errors in the distribution for large radii can introduce large errors in the determination of the central temperature). There is also some uncertainty in the results arising from the day-to-day variations.

Smerd⁵ has derived theoretical curves for the distribution of brightness for a number of wave-lengths, assuming the coronal electron density, N , given by Allen⁶ and a number of uniform temperatures, T . It is clear from a comparison of the observations with these theoretical curves that a coronal model with uniform temperature cannot account for the observations, and, in particular, that it cannot provide sufficient intensity at large radii.

If the electron density derived by Allen is retained, analysis showed that these discrepancies could not be removed by assuming that the temperature varied with height in the corona. A new method of analysis was therefore adopted in which no assumptions were

seen that a satisfactory fit is obtained for $p > 1.5 R_s$ (where p is the distance from the centre of the disk), which is the important region where Smerd's curves show the greatest discrepancy with observation. For values of p between $0.5 R_s$ and $1.5 R_s$, the intensity at 1.4 and 3.7 metres is somewhat greater than that observed. It seems likely, however, that this remaining discrepancy may be removed when it has been possible to allow for the effects of scattering by irregularities of electron density in the corona. Some information about these irregularities for $R > 5 R_s$ has recently been obtained by Hewish⁷ from observations of the occultation by the solar corona of the intense radio source in Taurus. It is possible that the inclusion of the scattering effects in the analysis may result in some modification to the values of N and T derived above.

This work was carried out as part of a programme of radio research at the Cavendish Laboratory, supported by the Department of Scientific and Industrial Research.

Television Pick-up Tube for both Light and X-Ray Pictures

INVESTIGATIONS carried out on television camera tubes using the photoconductive effect for converting a light image into an electrical signal have resulted in the development of an experimental tube sensitive to both visible light and to X-rays.

The photoconductive material used in the tube is suitably activated lead oxide, evaporated on a 'Pyrex' glass window. The layer is scanned by a low-velocity electron beam, as described by Weimer, Forgue and Goodrich¹.

The light sensitivity, the peak of which is in the blue part of the spectrum, amounts to about 100–200 microamp. per lumen when an incandescent light source at a colour temperature of 2,600° K. is used. The speed of response is sufficient to make the tube suitable for industrial applications and shows promise for application in television broadcasting.

The relatively good sensitivity to X-rays is the result of the high absorption coefficient of lead oxide for this radiation. A layer of only 5 microns thickness absorbs about 5 per cent of the radiation originating from an X-ray tube operated at 70 kV. D.C., the radiation being filtered by 5 mm. aluminium. The 1.2-mm. thick 'Pyrex' face on which the lead oxide has been applied absorbs about 10 per cent.

The accompanying photographs have been taken from a television monitor tube. Fig. 1 represents a

Fig. 1

Fig. 2

picture produced by the pick-up tube combined with a lens, the object being two identical transistors with a centimetre scale giving an impression of the dimensions. The 'scene' is illuminated with visible light. Fig. 2 shows a picture produced by the pick-up tube when the same transistors were placed in front of the tube face and irradiated by X-rays (X-ray shadow picture). The X-ray source consisted of a Philips's 'Practix' operated with 10 mA. at 72 kV. A.C. and placed at a distance of 70 cm. from the object. In the picture on the monitor tube the statistical noise of the X-ray quanta predominated over the amplifier noise.

It is thus possible to make an enlarged X-ray picture of small objects. The pick-up tube has a usable area of 20 mm. diameter, whereas the photograph was taken from a monitor with 35 cm. diagonal.

A Phase-Contrast Searcher for the Burch Reflecting Microscope

It is important in the ultra-violet microscopy of biological material to be able to search for and focus the specimen with visible light so that ultra-violet irradiation can be kept to a minimum. As the material examined is normally unstained, little detail can be seen using conventional illumination with the microscope.

To overcome this difficulty, the original Beck-Barnard ultra-violet microscope, produced in 1926, possessed a dark-ground illuminator built around the quartz condenser¹. The modern counterpart of this instrument, made by Cooke, Troughton and Simms, has a special phase-contrast condenser unit, and in this way an immersion visual phase-contrast objective can be used for preliminary viewing and focusing of the specimen². In the system designed by Walker and Davies³, focusing is performed in visual phase contrast with the aid of an auxiliary lens and phase plate, introduced behind the objective.

These systems have been used in conjunction with refracting objectives; but it is clear that a similar type of phase-contrast searcher would be of great use with the Burch reflecting microscope. The problem here is somewhat more difficult. By tracing a ray through the optical system, it can be shown that the small mirrors of the condenser and objective can be regarded as conjugate levels. Thus the annulus and phase plate could be ideally located at these mirrors. The introduction of these components to reproducible positions at the small mirrors presents serious mechanical difficulties and therefore was not attempted.

In the illumination system coupled to the Burch microscope, the condenser aperture is controlled by means of an aperture stop imaged at the condenser small mirror; thus the annulus can be located conveniently at this stop. In a similar way, it becomes necessary to image the objective small mirror to a more accessible position. In the system designed by Payne⁴, an image of the back focal plane of an

Optical system for phase contrast (not to scale)

objective is formed in an accessible position by means of a concave mirror, the light being deflected to a side tube attached to the microscope. Francon and Nomarski⁵ introduced phase contrast in the microscope by means of an eyepiece system, a projection eyepiece forming an image of the back of the objective at the phase plate, which was of strip form. Due to the long optical tube-length (34.5 cm.) of the Burch reflecting microscope, such a lens at the eyepiece level would produce an exceedingly small image of the annulus if the optical system was to be kept to a reasonable length.

To overcome this difficulty, without deflecting the light to a rather inconvenient side-tube, the system shown in the diagram has been adopted. The lens *L*, situated within the microscope body-tube, images the objective small mirror *O* at the phase plate *P* at approximately unit magnification. This lens also causes the main image-forming beam to converge at *X*. The phase plate is attached to the front surface of a low-power microscope objective *M* (3 in. focal length), which is focused on the image of the specimen at *X*. Thus the final image viewed through an eyepiece *E* appears under phase-contrast illumination. The definition of the image is good, but the curvature of field is rather high, the low-power microscope objective introducing field curvature additional to that of the reflecting objective itself. This has the effect of reducing the diameter of flat field from about 140 μ to 70 μ , a defect which is of little importance for searching purposes.

In the actual system used on the microscope, the lens *L* is a telescope objective of short focal length and has not been specially computed for the purpose. It produces a well-corrected image of the specimen; but in forming an image of the annulus, the lens is working at conjugates for which the correction is poor. It is therefore advisable for the phase ring to be wide relative to the annulus; chromatic aberration, which produces colour over the whole object field, can be restricted by using green light.

This auxiliary optical system can be introduced into the microscope quite easily. The lens *L* is swung into the light beam, while the tube containing phase plate, microscope objective and eyepiece fits into the eyepiece tube of the Burch microscope. Set up in this way, the system greatly facilitates searching the specimen, prior to photomicrography and absorption measurements in the ultra-violet.

This work has been supported by grants to the Royal Cancer Hospital and Chester Beatty Research Institute from the British Empire Cancer Campaign, the Jane Coffin Childs Memorial Fund for Medical Research, the Anna Fuller Fund, and the National Cancer Institute of the National Institutes of Health, U.S. Public Health Service.

Crystal Structure of Glycyl-L-Alanine Hydrobromide

INTEREST in the crystal structures of simple peptides has increased considerably, during recent years on account of progress made in the direct investigation of protein structure. Glycyl-L-alanine hydrobromide has been prepared in these laboratories and examined by X-ray methods. The free dipeptide was prepared by the N-carbobenzoxy method¹ and then converted into the hydrobromide which crystallized readily from aqueous solution.

The crystal data for glycyl-L-alanine hydrobromide are $a = 10.89$ Å.; $b = 6.13$ Å.; $c = 7.63$ Å.; $\beta = 108^\circ 34'$. The density (by flotation) is 1.714 gm./c.c. The number of molecules per unit cell is 2 mol. glycyl-L-alanine + 2 mol. of water of crystallization. Space group, P_1 .

The intensities of 154 Å. reflexions were measured visually using copper $K\alpha$ radiation, and the Patterson projection on (010) showed a clearly resolved peak attributable to the Br-Br vector. From the position of the heavy atom the signs of a large proportion of the structure factors could be derived, and from the preliminary Fourier projection the signs of the

Fig. 1

Fig. 2

remaining terms were obtained. The resulting projection is shown in Fig. 1 and is adequate for placing the atoms in the unit cell, with all the atoms, including the water molecule O_4 , being resolved with the exception of C_1 and O_3 (see Fig. 2).

A preliminary examination of the structure using y -co-ordinates derived by assuming probable bond-lengths for the glycyl-L-alanine molecule showed satisfactory hydrogen-bonding, the glycyl-L-alanine and water molecules forming spirals bound together laterally by N—H bonds. A detailed discussion of this aspect will, however, be postponed until the structure has been refined using the hydrochloride, which is isomorphous with the hydrobromide.

Formulation of the Rate Equation in Chemical Kinetics

ROBB¹ has recently pointed out that when the rate-constant for a reaction such as

is under discussion, it is necessary to state whether the rate referred to is the disappearance of A or of B , since the latter is half as fast as the former.

It is perhaps also worth pointing out that in the academic literature of reaction kinetics, rates are always written as rates of change of concentration in a closed system which is tacitly assumed to be at constant volume; for example:

$$-\frac{d}{dt}[A] = -2\frac{d}{dt}[B] = k[A]^2[B]. \quad (1)$$

This equation has only limited application to industrial processes. There are closed reaction systems, for example, in which the volume changes during the reaction, and open systems (such as continuous-flow tank and tubular reactors) in which the concentration is independent of time². The rate-equation is more generally useful when written in a less restricted form; for example:

$$-R_s = -2R_b = \frac{k}{V^2} \cdot a^2b. \quad (2)$$

The system to which this equation applies may be open or closed, but has a constant atomic content, and is assumed to be virtually uniform in composition and temperature. At a given instant it has volume V and contains a, b moles of A, B . $-R_s$, $-R_b$ are the rates of destruction of A, B by the reaction. k has the same significance and value as in equation (1).

In a closed system, $R_s = da/dt$; V may be a function of a, b, t . Equation (2) is then to be integrated accordingly. In a flow-system operating at steady state, V, a, b and R_s are constant, the latter being the difference between the rates of inflow and outflow of A . Other variants may also be encountered.

A Competitive Method of determining Association Constants

THE method described by Benesi and Hildebrand¹ for determining the association constants of charge-transfer complexes involves optical measurements of a series of solutions at or near the wave-length of maximum absorption of the complex. A simple method for determining such constants which avoids these conditions has been devised.

Consider the two interactions:

involving two Lewis bases B' and B'' and a Lewis acid A (or vice versa). An equilibrium constant K may be defined as:

$$K = \frac{[AB]}{([A] - [AB])([B] - [AB])} \quad (1)$$

where $[A]$ and $[B]$ are the initial concentrations of A and B . For simplicity, let $[B'] = [B''] = [B]$, say, then if $[B] \gg [A]$:

$$K' = \frac{[AB]}{[B]([A] - [AB] - [AB'])} \quad (2)$$

$$\text{and } K'' = \frac{[AB]}{[B]([A] - [AB'] - [AB''])} \quad (3)$$

Eliminating $[AB']$ from equations (2) and (3):

$$[AB'] = \frac{K[A][B]}{1 + K[B] + K'[B]}. \quad (4)$$

A wave-length is selected at which the species A, B', B'' and AB' have negligible absorptions, but at which AB' absorbs (preferably at or near the maximum of the charge-transfer spectrum of this species). If the extinction coefficient of the species AB' at this wave-length is ϵ , then the optical density of a solution at this wave-length will be $D = \epsilon[AB']$.

The optical densities of two solutions, one containing A and B' at concentrations $[A]$ and $[B]$, the other containing A, B' and B'' at concentrations $[A], [B]$ and $[B]$, are measured at this wave-length. If D_1 and D_2 are the two optical density readings so obtained, then applying equation (4):

$$\frac{D_1}{D_2} = \frac{1 + K[B]}{1 + K[B] + K'[B]} \quad (5)$$

$$\text{or } K' = \frac{D_1 - D_2}{D_2} \left(K' + \frac{1}{[B]} \right). \quad (6)$$

Knowing K' , K'' may be determined.

Applying the method to the complex of N - n -butylaniline and s -trinitrobenzene by measuring the competition of the former with N - N - N' -tetramethyl p -phenylenediamine in cyclohexane, the following results were obtained:

$$[B] = 0.118 M; [A] \approx 10^{-4} M;$$

$$D_1 = 0.320 \text{ cm}^{-1} \text{ and } D_2 = 0.255 \text{ cm}^{-1} \text{ at } 650 \text{ m}\mu.$$

Using a value of $K = 20.4$ litres/mole for the association constant of N - N - N' -tetramethyl p -phenylenediamine with s -trinitrobenzene in cyclohexane (obtained by the method of Benesi and Hildebrand), a value of the association constant of N - n -butylaniline with s -trinitrobenzene in cyclohexane of 7.4 litres/mole is obtained. The value obtained by the method of Benesi and Hildebrand is 8.2 litres/mole.

FORTHCOMING EVENTS

(Meetings marked with an asterisk * are open to the public)

Monday, February 1

SOCIETY OF ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. W. R. Howard: Presidential Address.

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (in the Chemical Society's Rooms, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. J. W. Barrett: "Production and Development of Chemicals for the Rubber Industry".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the ALKEMIC CLUB, in the Physical Chemistry Laboratory, Oxford), at 8.15 p.m.—Mr. A. R. Powell, F.R.S.: "The Platinum Metals".

Tuesday, February 2

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. M. Mary Douglas: "Primitive Medicine among the Lale of the Belgian Congo".*

INSTITUTION OF CHEMICAL ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. J. E. Richardson and Mr. W. K. Zaki: "Sedimentation and Fluidization".

ROYAL INSTITUTE (at 21 Albemarle Street, London, W.1), at p.m.—Prof. H. Munro Fox, F.R.S.: "Colour in Animals". (Further lectures on February 9, 16 and 23.)

Wednesday, February 3

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. J. G. Capewell: "The Post-Silurian re-Marine Carboniferous Sedimentary Rocks of the Eastern Side of the English Lake District". Dr. F. W. Anderson and Dr. V. Wilson: "The Occurrence of Algal Beds in British Paleozoic and Mesozoic Rocks".

INSTITUTION OF MECHANICAL ENGINEERS (at Storey's Gate Station, London, S.W.1), at 6.45 p.m.—Internal Combustion Engine Group Discussion: "The Extent to which the Gas Turbine may Supplant or Supplement the Piston Engine in the Next Ten or Twenty Years".

Thursday, February 4

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. J. Maynard Smith: "Mendel, Michurian and Hybrid Vigour".*

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 2.30 p.m. and 7.30 p.m.—Symposium on "Kinetics and Mechanism of Inorganic Reactions in Solution. A Survey of Recent Work".

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. J. C. Bevington, Mr. G. M. Guzman, and Prof. F. W. Melville, F.R.S.: "Self-branching in the Polymerization of styrene and of Vinyl Acetate"; Mr. P. Alexander, Mr. A. Charnishy, and Mr. M. Bess: "The Degradation of Solid Polymethylmethacrylate by Ionizing Radiation".

LINEAN SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. R. Melville: "Plant Hunting Across Australia, 1953-1954".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. G. Dawson, Mr. L. L. Hall, Mr. K. G. Hodgson, Mr. R. A. Meers, and Mr. J. H. H. Martin: "The Manchester-Kirk of Shotts Television Radio Relay System".

ROYAL METEOROLOGICAL SOCIETY (in the Conference Hall, County Hall, Westminster Bridge, London, S.E.1), at 5.30 p.m.—Mr. J. S. Sawyer: "Weather Forecasting".*

UNIVERSITY OF LONDON (at the School of Pharmacy, 17 Bloomsbury Square, London, W.C.1), at 5.30 p.m.—Prof. J. H. Gaddum, F.R.S.: "Discoveries in Pharmacology".* (Further Lecture on February 5.)

UNIVERSITY OF LONDON (at Senate House, London, W.C.1), at 8.0 p.m.—Air Marshal Sir Harold Whittingham: "Medical Science and Problems of Flying".* (Further Lecture on February 11.)

UNIVERSITY OF LONDON (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. F. Bergal: "Some Chemical Aspects of Abnormal Growth".* (Further Lecture on February 9.)

INSTITUTE OF METALS, LONDON LOCAL SECTION (at 4 Grosvenor Gardens, London, S.W.1), at 6.30 p.m.—Mr. R. W. Douglas: "Germanium and Silicon".

INSTITUTE OF WELDING, NORTH LONDON BRANCH (at Manson House, Orford Place, London, W.1), at 7 p.m.—Dr. R. Week: "Avoiding slag in Welded Structures".*

Friday, February 5

SOCIETY OF COMBUSTION CHEMISTS OF GREAT BRITAIN (at the Royal Society of Tropical Medicine and Hygiene, 25 Portland Place, London, W.1), at 7 p.m.—Prof. W. D. Wright: "Colour and Colour Vision".

POLISH CULTURAL INSTITUTE (at 81 Portland Place, London, W.1), at 8 p.m.—Dr. M. J. Beaton: "The Copernican Controversy and its significance for Modern Science".*

ROYAL INSTITUTE (at 21 Albemarle Street, London, W.1), at p.m.—Prof. M. Postan: "Medieval Science and Technology".

Saturday, February 6

LONDON COUNTY COUNCIL (at the Hornman Museum, London Road, Great Hill, London, S.E.23), at 3.30 p.m.—Mr. M. Freedman: "Death and Marriage Among Chinese in Singapore".*

BRITISH INTERPLANETARY SOCIETY (in the York Hall, Caxton Hall, Westminster, London, S.W.1), at 6 p.m.—Mr. K. W. Gatlend: "Progress Towards Astronautics".*

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned.

ASSISTANT LECTURER IN CHEMISTRY, at the University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education in the Colonies, 1 Gordon Square, London, W.C.1 (February 6).

EXPERIMENTAL OFFICER (Physicist or Metallurgist) (with at least H.S.C. (science), or equivalent, but degree in metallurgy or physics may be an advantage), for work on X-ray diffraction in the METALLURGY DIVISION—The Establishment Officer, Atomic Energy Research Establishment, Harwell, Berks, quoting 2/103/4 (February 6).

HEAD (graduate in science, engineering or mathematics, and with suitable experience in the textile industry) OF THE TEXTILE DEPARTMENT, Bolton Technical College—Chief Education Officer, Education Office, Nelson Square, Bolton (February 6).

HEAD (with honours degree in chemistry, and textile experience, preferably in the hosiery trade) OF THE CHEMISTRY DEPARTMENT—The Secretary, Hosiery and Allied Trades Research Association, 4 First Avenue, Sherwood Rise, Nottingham (February 6).

PHYSICISTS, Scientific Officer grade (with first- or second-class honours degree, or equivalent), or **Experimental Officer grade** (with H.S.C. (science), or equivalent), in Ministry of Supply Research and Development Establishments, to apply their knowledge to problems from many fields, including aerodynamics and aircraft structures, aircraft instruments, armaments, electronic circuits, radio and radar—The Ministry of Labour and National Service, Technical and Scientific Register (R), 26 King Street, London, S.W.1, quoting A1/54A (February 6).

SENIOR LECTURER (preferably with knowledge of applied chemistry) IN INORGANIC CHEMISTRY—The Registrar, Nottingham and District Technical College, Shakespeare Street, Nottingham (February 6).

LECTURER (graduate in chemical engineering, or graduate in chemistry, with postgraduate training and/or experience in chemical engineering) IN CHEMICAL ENGINEERING—The Registrar, College of Technology, Manchester 1 (February 8).

FIRST ASSISTANT STATION CHEMIST (preferably with university degree or A.R.I.C.), at Barton Generating Station, Manchester—The Establishments Officer, British Electricity House, 835 Wilmslow Road, Manchester 20, quoting "Vacancy No. 6-54" (February 13).

SCIENTISTS, Grade II or III (with first- or second-class honours degree, or equivalent, in engineering, mathematics or physics, and some experience in field or laboratory research) IN THE FIELD INVESTIGATION GROUP, to carry out field work at collieries—The National Coal Board, Establishments (Personnel), Hobart House, Grosvenor Place, London, S.W.1, quoting IT/7/29 (February 13).

ANALYTICAL CHEMIST IN THE DEPARTMENT OF AGRICULTURAL CHEMISTRY—The Registrar, Wye College, near Ashford, Kent (February 15).

CHAIR OF BOTANY—The Registrar, University College, Singleton Park, Swansea (February 16).

MAY AND BAKER RESEARCH FELLOW (with qualifications in plant pathology, and some postgraduate research experience) to undertake research work under the direction of the Professor of Agricultural Chemistry, on fungicides and systemic fungicides (including field trials)—The Registrar, Wye College, near Ashford, Kent (February 15).

ASSISTANT LECTURER IN APPLIED MATHEMATICS—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (February 20).

CHAIR OF ELECTRICAL ENGINEERING—The Registrar, The University, Nottingham (February 20).

LECTURER IN BACTERIOLOGY, and an **ASSISTANT LECTURER IN CHEMISTRY**—The Registrar, Trinity College, Dublin (February 20).

PRINCIPAL SCIENTIFIC OFFICER (with an honours degree in science or civil engineering, and a knowledge of applied mathematics and physics, and preferably with experience in the application of soil mechanics to civil engineering design and construction) in the Air Ministry, for work on soil mechanics at Church Lawford, Warwickshire—The Ministry of Labour and National Service, Technical and Scientific Register (R), 26 King Street, London, S.W.1, quoting R.41/54A (February 20).

ASSISTANT NUTRITIONIST (non-medical) (with B.Sc. in biological sciences, and some teaching and research experience), for evaluating dietaries, analysing field data, abstracting papers, preparing reports and assisting in teaching tropical nutrition and dietetics—The Director, Applied Nutrition Unit, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1 (February 22).

READER IN MORBID ANATOMY, tenable at London Hospital Medical College—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 22).

HEAD (with good honours degree, and teaching experience) OF THE MATHEMATICAL DEPARTMENT—The Registrar, The Royal Belfast Academical Institution, Belfast (February 23).

LECTURER IN PSYCHOLOGY at New England University College, Armadale, New South Wales, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Armadale, March 1).

ROBERT BLAIR FELLOWSHIP tenable for one year of advanced study or research abroad in Applied Science or Technology—The Education Officer (EO/H/1/2), County Hall, London, S.E.1 (March 1).

LECTURER IN THE DEPARTMENT OF CHEMISTRY, Victoria University College, Wellington, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Wellington March 5).

CHAIR OF GEOGRAPHY—The Registrar, University College of Leicester, Leicester (March 6).

READER (with high academic qualifications, and research experience in theoretical physics, preferably in quantum theory) IN THEORETICAL PHYSICS, at the University of Western Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Australia, March 22).

TURNER AND NEWALL RESEARCH FELLOWSHIP IN ENGINEERING, INORGANIC CHEMISTRY OR PHYSICS, or other allied science—The Registrar, The University, Leeds 2 (April 21).

ASSISTANT DIRECTOR, to take charge of a team of chemists, physical chemists, physicists and mathematicians, engaged on a comprehensive scientific study of the physical and chemical properties of rayon and synthetic fibres, and problems associated with the application of these fibres—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, Manchester.

BRITISH RUBBER PRODUCERS' RESEARCH FELLOW (with a good honours degree in engineering or physics, and industrial or research experience) for research into the mechanical properties of rubber—The Registrar, The University, Nottingham.

ENGINEERS, PHYSICIANS, PHYSICAL CHEMISTS AND METALLURGISTS (Senior Scientific Officer and Scientific Officer grade) (with an appropriate first- or second-class honours degree or equivalent high professional attainments) in Royal Naval Scientific Service Experimental Establishments in the London, Portsmouth, Weymouth and Gloucestershire areas, and Scotland—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.246/82A/T7.

EXTENSION LECTURER (with high academic qualifications in pure science, preferably in physics or chemistry) IN SCIENCE, to lecture at an advanced level to science graduates in industry, etc., principally in Cumberland—The Director of Extra-Mural Studies, King's College, Joseph Cowen House, 153 Barras Bridge, Newcastle-upon-Tyne 1.

LECTURER (with a good honours degree in applied or pure science, and research and industrial experience) IN MECHANICAL ENGINEERING—The Registrar, The University, Nottingham.

MATHEMATICS MASTER (with high honours degree)—The Head Master, Lancing College, Shoreham-by-Sea, Sussex.

METALLURGIST (with a degree in metallurgy or equivalent qualification, and preferably with previous industrial experience) for work entailing the application of research results in industrial practice—The Secretary, British Non-ferrous Metals Research Association, 50-51 Ruxton Street, London, N.W.1.

MINING GEOLOGIST (with B.Sc. degree with honours in mining geology) in the Colonial Geological Survey Service, Sierra Leone, for duties which include search for new mineral deposits, mapping, petrology and mineralogy of known mineral deposits, geological mapping, geophysical prospecting by resistivity and magnetometry—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting CDB.105/15/02.

PHYSICIST (with first- or second-class honours degree in an appropriate scientific subject, of a United Kingdom or Commonwealth University, or an equivalent qualification) IN THE COLONIAL INVENTORIES RESEARCH UNIT, at the Ministry of Supply Chemical Defence Experimental Establishment, Porton, near Salisbury, to undertake research work in connection with the application of chemical formulations for the control of pests of public health and agricultural importance—The Under-Secretary of State, Research Department (8.610), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

PHYSICISTS (with good honours degree, and some experience or training in research, not necessarily in textile research), for work on textile problems—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, near Manchester.

SCIENTIFIC OFFICERS (with first- or second-class honours degree in a suitable subject, or equivalent qualifications) in the Department of Scientific and Industrial Research, Mechanical Engineering Research Laboratory, Bant Kilbride; **MATHEMATICIAN OR MECHANICAL ENGINEER**, for work on stress distribution and fatigue problems (Ref. C.16/54A); **ELECTRICAL ENGINEER OR PHYSICIST**, for work on application of noise control techniques to the suppression of noise in machinery (Ref. D.30/54A); **PHYSICIST OR PHYSICAL CHEMIST** (with sound knowledge of classical thermodynamics) for preparation of thermodynamic tables (Ref. A.11/54A); **ENGINEER OR PHYSICIST**, for investigation into the fundamental mechanism of plastic deformation of materials (Ref. A.12/54A)—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting appropriate Ref. No.

SHANDON

SOLVING YOUR CENTRIFUGING PROBLEMS

Here is a range of high-speed Centrifuges for handling the many difficult separating problems which are met increasingly throughout the field of scientific investigations.

PHYWE ULTRA CENTRIFUGE 50,000 r.p.m. 180,000 $\times$ g.

The latest model of this Centrifuge, incorporating a great number of refinements, is now available as—

- (A) Preparative Centrifuge with water-cooling and thermo-magnetic temperature control, carrying either a 50,000 r.p.m. rotor for six 7.5 ml. tubes or a 30,000 r.p.m. motor for sixteen 7.5 ml. tubes.
- (B) Analytical Centrifuge, as illustrated above, with improved optical equipment for the Toepler, Philpot-Svensson or Lamm methods, and new control unit for greater operating convenience, without sacrificing the easy accessibility of the Centrifuge proper.

PHYWE SEMI-ULTRA CENTRIFUGE 14,500 r.p.m. 27,000 $\times$ g.

This Centrifuge is available with water-cooling or complete refrigerating system, the latter being capable of maintaining a rotor temperature of 0° C. at maximum speed. There is a choice of two interchangeable angle heads, one carrying six 50 ml. tubes and the other twenty 12½ ml. tubes.

SHANDON MICRO CENTRIFUGE 20,000 r.p.m. 25,000 $\times$ g. the first low-priced high-speed Centrifuge

The Shandon Micro Centrifuge has been specially designed for the micro-biologist and micro-chemist and will prove exceedingly useful when dealing with small quantities of liquid, either by choice or necessity. It offers also a convenient means of re-centrifuging the supernatant obtained from ordinary centrifuges. The Micro Centrifuge is water-cooled and available with two interchangeable rotors carrying either six 3.3 ml. or eight 1 ml. tubes, and covers, of course, the whole speed range from 1,000 to 20,000 r.p.m.

Optical Fused Quartz

Transparent fused quartz can be supplied for optical purposes as blanks for plates, lenses, prisms, etc., or as finished optical elements up to the highest degree of optical finish and freedom from strain.

It is manufactured in various grades, thus providing a suitable quality for each class of work ranging from the most exacting uses in ultra-violet optical determinations to ordinary work in the near ultra-violet and infra-red regions. We shall be pleased to recommend a suitable quality for your particular application.

PROTECTION OF BIRDS IN BRITAIN

IN Great Britain there are two main sets of laws dealing with the protection of birds—the Game Acts and the Wild Birds Protection Acts.

In contrast to some other European countries, where game birds may include thrushes, skylarks and even grebes, game birds in England and Wales are strictly defined in the main Game Act of 1831, which designates black game, bustard, grouse, partridge and pheasant under this heading, and lays down the close times which are to be observed for these species. In addition, game birds are also subject to strict controls regarding sale, possession, trespass and so on, and can only be shot by those possessing a game certificate, whereas for wild birds a gun licence only is necessary. Duck, geese and waders, although shot for sport, are not designated as game and are covered by the Wild Birds Protection Acts. Woodcock, snipe, quail and landrail, though not designated as game in the Act of 1831, and the close times of which are regulated by the Wild Birds Protection Acts, are, however, included in some of the provisions of the Game Acts, and it is necessary to possess a game certificate to shoot them.

The Wild Birds Protection Act of 1880 superseded all previous Acts for the general protection of birds and formed the main basis of legislation. In the ensuing fifty years, thirteen further Acts for the protection of birds were made law; further, in the course of time, 260 local orders have been added making various alterations regarding close times, etc. The Acts of Parliament have to be read together with the local order to ascertain what amount of protection any particular bird may have—and, in short, the law is so complicated and unwieldy that few people understand it, much less enforce it.

The need for new legislation has been recognised for nearly half a century. So long ago as 1914, a departmental committee was appointed by the Home Secretary under the chairmanship of the Right Hon. E. S. Montagu, M.P., to make recommendations for clearing up the confusion of the bird protection laws. This committee made its report in 1919; but since that date, six further Acts have been passed. Various societies and individuals have sought to introduce new measures to end the existing state of confusion, and committees after committees of ornithologists and other experts have spent much time and trouble in drawing up reports to this end. But the years have passed without any result from their labours.

After the War the Home Office Wild Birds Advisory Committee was reconstituted under the chairmanship of the Earl of Ilchester and continued the work of preparing a single Bill for the Protection of Birds, which would incorporate and simplify all necessary provisions contained in existing legislation with the addition of further provisions to meet modern requirements. Concurrently, a Scottish Wild Birds Advisory Committee worked on the same lines, and the agreed proposals of the two Committees form the main provisions of two Bills placed before Parlia-

ment, one in the House of Lords, sponsored by Viscount Templewood, which received its second reading on November 11, 1953, and a private member's Bill in the Commons, sponsored by Lady Tweedsmuir, which received its second reading on December 4, 1953.

Under both these Bills, no less than fifteen complete Acts of Parliament and also parts of several more are repealed, which gives some idea of the much greater simplification and clarity which should result.

The two Bills, being based on the proposals made by the Advisory Committees, are very similar and only vary in certain details. The fundamental provision is the change to the modern conception of affording protection throughout the whole year to all birds, excepting those causing damage, which may be killed at any time, and also those which are termed 'sporting birds' and may be killed during certain periods of the year only. The principle of departing from the old system of making long lists of birds which are to receive protection has already been adopted by other countries, notably by Northern Ireland in 1931, and forms the basis of the International Convention for the Protection of Birds which was signed *ad referendum* by the representatives of twelve European countries in Paris in 1950 (*Nature*, 167, 173; 1951). Under the old system, if a rare bird appeared in Great Britain it was not legally protected unless it happened to be mentioned in a list, either statutory or local; but under the new provision all rarities will be automatically provided for under the omnibus protection accorded to all birds.

Four schedules are added to the Bills. The first contains the very rare species, the killing or taking of which at any time is subjected to increased penalties. A second part of this same schedule contains a list of species considered as sporting birds but which, though not uncommon, rarely breed in Great Britain. They are, therefore, during the breeding season, given the additional safeguard of increased penalties, though they may legitimately be killed at other times. The special penalties also apply to the taking of eggs of all birds in this schedule. The second schedule contains a list of birds which are considered harmful in one way or another and which may be killed at any time. In order to avoid the wholesale destruction of such birds, the power to destroy them is limited to owners and occupiers of land, and certain statutory bodies, or persons authorized by them. The third schedule contains a list of the sporting birds which may be shot outside a specified close season, and the fourth schedule consists of birds which may not be sold alive, unless they are close-ringed specimens bred in captivity. This last schedule is a re-enactment of the Bird Protection Act 1933, which was designed to stop the traffic in British wild birds.

In the past, legislation with regard to bird protection has proved far too inelastic, and with rapidly changing conditions this state of affairs is unworkable. A common species may become scarce; or a species which is quite innocuous in small numbers may become the reverse if there is a large increase.

In the present Bills, allowance is made for such changes by investing the Secretary of State with the power to make any necessary adjustments to the schedules. Exceptions to the provisions of the Bills may also be made, by means of licences, for science, education and so on; and agriculture, fisheries and other interests are safeguarded. Statutory committees on wild birds to advise the Secretaries of State for England and Scotland are to be appointed.

In the past, certain methods of taking and killing birds have been prohibited, mainly on account of the cruelty involved, and these prohibitions have been incorporated in the Bills. To these have been added certain other methods which are prohibited, not so much on account of any cruelty involved, but to avoid undue slaughter of birds in large numbers and to make the odds brought about by modern methods of destruction less heavy against the quarry.

The need for an international point of view in bird protection is now generally recognized, and this is provided for in the new Bills by restrictions on the import of certain birds and eggs, and power is given to the Secretary of State to prohibit the import of any bird or egg for the whole or part of a year. In this way international co-operation with any country which is endeavouring to prevent the exploitation of any species can be achieved; a precedent for this was made in the Protection of Quails Act, 1937, which prohibited the import of live quails during certain months, a measure in support of the action taken by the Egyptian Government in prohibiting the export during the same period.

It is generally accepted that the commercialization of a species is its greatest danger, and to this end restrictions are placed on the sale of certain birds, alive or dead, and the sale of eggs of birds which have nested in the British Isles (those of certain gulls only excepted).

The question of the protection of wild birds' eggs is one of great difficulty. In the International Convention for the Protection of Birds, the general policy of according the same protection to eggs as to birds themselves is followed, subject to certain exceptions, and this method has been adopted with success in other countries, including Australia. The Wild Birds Advisory Committee, on the whole, also took this view; but a very decided opposite opinion has been voiced by many people, including the Government spokesman, the contention being that it is highly undesirable to create a criminal offence in a young boy taking a common bird's egg. That this state of affairs already exists in a large number of counties, in some of which practically every British nesting bird's egg is protected by county order, does not alter this view. This difficult question has been dealt with in different ways in the two Houses; in the House of Lords' Bill, only eggs of the rare birds (Schedule 1) are protected by statute, but power is given to the Secretary of State to prohibit by Order, affecting the whole or part of Great Britain, the taking or destruction of the eggs of any wild bird specified. This maintains the present situation so far as eggs are concerned, and retains the long local lists which it is so desirable to eliminate.

In the Commons, the other approach has been taken of according protection to the eggs of all wild birds except for those of the harmful birds (Schedule 2) or "of any other common wild birds which the Secretary of State may by Order made with respect to the whole or any specified part of Great Britain prescribe for the purposes of this paragraph". This again is not a simple solution, for a list of birds' eggs which may be taken is, in the opinion of some people, a direct incentive to plunder birds' nests; moreover, to draw up such a list would be a far from easy task.

In the Bills, power to establish bird sanctuaries is given to provide for such areas which are not covered by the National Parks Act of 1949, enforcement of the law is made simpler and penalties for infringement are increased in accordance with present-day standards.

The Game Laws are in no way affected by the Bills except in so far as they mention the landrail and quail. These two species, having become very scarce, are included in the first schedule of the new Bills; the relevant passages regarding the shooting of these birds in the Game Acts 1831, 1832 and 1860 are therefore repealed.

Legislation in Great Britain for the protection of birds, as has been said, has become involved and cumbersome, and a revision was overdue. The present Bills, while not wholly satisfactory, seem to provide, in their different ways, for the protection of birds, and are in line with international feeling on the subject; it is to be hoped that there will be no undue delay in one or other reaching the Statute Book.

THE CASE FOR NATURAL SELECTION

Evolution In Action

Based on the Patten Foundation Lectures delivered at Indiana University in 1951. By Dr. Julian Huxley. Pp. 160. (London: Chatto and Windus, 1953.) 9s. 6d. net.

IN a very short time biologists, all over the world, will celebrate the centenary of "The Origin of Species by means of Natural Selection". There may be some heart-searching; there will certainly be a great deal of discussion.

Darwinian orthodoxy demands implicit faith in the efficacy of natural selection operating on chance mutations. Subscribe to this and all doubts and hesitations disappear; question it and be forever lost. The case for orthodoxy can seldom have been stated with greater cogency and enthusiasm than by Dr. Julian Huxley in "Evolution in Action". A few readers, perhaps rather pagan in their outlook, may think it a little strange that, if the case is quite so strong as they are asked to believe, it should still be necessary to argue the merits of natural selection with almost evangelistic vigour.

On one point all biologists are agreed: the basic concept of organic evolution has, for a century, stood unrivalled as a contribution to biological thought. As a working hypothesis it opened up and exploited vast new fields of palaeontological, anatomical and embryological inquiry. The status of natural selection is not quite so high. True, it is the only theory we

have; but when judged as a working hypothesis it is disappointing to find so little advance in a hundred years. What new facts have been brought to light? How far can it be shown to have elaborated the pageantry of animal life since 1859? A century is a fantastically short period of cosmic time, and all sorts of queer, exciting and improbable things may happen in five hundred million years; so, if we accept 'possibility' as a basis for scientific thought, why worry? Dr. Huxley admits quite frankly: "No one would bet on anything so improbable happening; and yet it *has* happened. It has happened thanks to the workings of Natural Selection and the properties of living substance which make Natural Selection inevitable". What more can be said, except possibly to suggest that there may be a slight difference between something that 'has happened' and one which 'may have happened'. No amount of argument, or clever epigram, can disguise the inherent improbability of orthodox theory; but most biologists feel it is better to think in terms of improbable events than not to think at all; there will always be a few who feel in their bones a sneaking sympathy with Samuel Butler's scepticism: "... there must have been a little cheating somewhere with these accidental variations [mutations] before the eagle could have become so great a winner". How far the heathen will be converted by Dr. Huxley is difficult to say.

The theory of natural selection implies the survival of organisms possessing functional advantages over their predecessors or rivals. Strange as it may seem, one immediate effect of the "Origin" was a marked recession in the study of animal function. There was, and still is, a tendency for morphologists to ascribe to organs and structures functional significance for which there was, or is, little observational evidence. In this respect "Evolution in Action" is by no means guiltless; it goes a considerable way beyond the physiological facts. Is Dr. Huxley quite sure that the loss of the lateral digits by the ancestors of the horse gave them an "additional turn of speed"? And, is he certain that the parallel between increasing complexity of anatomical structure (so clearly displayed throughout vertebrate evolution) and increasing complexity or versatility of behaviour is quite so obvious as he suggests? In what ways is the behaviour of a frog, a lizard, or even a sheep, an 'advance' on that of a stickleback? What about the hoary old story of snakes walking by their ribs?

To lay readers the more exciting part of "Evolution in Action" deals with the position of man in relationship to the rest of the animal world. To Dr. Huxley, man is an organism in a class apart from all others. In many ways man is more distinguished; but most readers will be sorry to read that "the human species to-day is burdened with many more deleterious mutant genes than can possibly exist in any species of wild creature". It seems a great pity that natural selection should have met its Waterloo just when it was most needed.

In the jungles of the past Nature guards her secrets with particular care, and it is a brave man who ventures far from the recognized tracks; it is so much easier to sit and criticize more adventurous spirits. Dr. Huxley's aim is not to comfort the despondent but to hit the dragons of Improbability stoutly on the nose and to give the world "a real feeling of the unity and sweep of evolution... as a self-transforming process... building its future by transcending its past". He has succeeded.

J. GRAY

CARBOHYDRATE CHEMISTRY

Advances in Carbohydrate Chemistry

Edited by Claude S. Hudson, Melville L. Wolfrom, Sidney M. Cantor. Vol. 7. Pp. ix+370. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1952.) 7.50 dollars.

SINCE the first volume of "Advances in Carbohydrate Chemistry" was published in 1945, this series has established itself as indispensable both to those who work in this field and to those workers in other fields who wish to be well informed about sugar chemistry. The present volume maintains the high standard set by earlier volumes of the series. It contains eight articles, five from Britain, two from the United States and one from Germany.

The first of the articles, "The Methyl Ethers of the Aldopentoses and of Rhamnose and Fucose", contributed by R. A. Laidlaw and (the late) E. G. V. Percival, continues the series on the methyl ethers of the sugars started in earlier volumes. Methylation remains the backbone of structural studies in carbohydrate chemistry; this authoritative article will be of particular interest to those engaged in structural studies of the naturally occurring pentoses and of plant gums and mucilages.

The second article, "1,6-Anhydrohexofuranoses, a New Class of Hexosanes", by R. J. Dimler, concerns two compounds, β -glucosan $<1,4>\beta<1,6>$ and β -galactosan $<1,4>\alpha<1,6>$, which are of considerable interest in that they contain a 1,2-glycol system which is not attacked by sodium metaperiodate. This observation is important in view of the widespread use of and increasing dependence on this reagent to detect 1,2-glycol systems; but I am inclined to the opinion that the article would have been more valuable had it been delayed until work designed to test some of the theories advanced to explain this resistance to oxidation had been completed.

The next two articles concern the ketoses. C. P. Barry and J. Honeyman review "Fructose and its Derivatives", and J. V. Karabinos reviews "Psicose, Sorbose and Tagatose". Both articles give excellent accounts of their subjects, although the addition of a discussion of the fructose phosphates, especially of fructose 1,6-diphosphate, would have been welcome in view of their biochemical importance. No mention is made of the tagatose 6-phosphate described towards the end of 1949 by Totton and Lardy¹. Since Dr. Karabinos's review contains only two references (probably added in proof) to papers appearing at a date later than 1949, it is probable that this publication of Totton and Lardy appeared after the review was completed. If this is so, then the delay between the completion of the article and its publication is considerable and strengthens my opinion that all articles of this type should bear the date of receipt of the manuscript by the editors.

The fifth article, "Acetals and Ketals of the Tetritols, Pentitols and Hexitols", by S. A. Barker and E. J. Bourne, is a valuable account of the preparation and properties of these compounds and includes an interesting discussion of the most probable manner in which a given carbonyl compound would condense with a given polyhydric alcohol. The sixth article, "The Glycols", by B. Helferich, has been translated by W. Pigman from the original German. The unsaturated sugar derivatives are not as widely known as they might be, and it is to be

hoped that this article on glycols will be followed fairly soon by one on the glycoosanes. "The Chemistry of the 2-Amino Sugars (2-Amino-2-Deoxy-Sugars)" is discussed by A. B. Foster and M. Stacey. Members of this group of compounds are of considerable interest, both intrinsically and as structural components of the mucopolysaccharides.

All these seven articles in the volume give long and apparently exhaustive tables of selected physical constants of derivatives of the compounds under review.

The final article, "The Size and Shape of some Polysaccharide Molecules", by O. T. Greenwood, reviews the application of physical methods to the determination of the molecular weights of polysaccharides other than starch and cellulose and shows the importance of the use of all possible methods of study before hazarding any suggestion as to the structure of any polysaccharide. In this article I found that the editorial policy of the use of expressions of the type $(0.7)10^4$ and $0.7(10)^4$ in place of the more familiar 0.7×10^4 was at first confusing and later irritating.

The articles as a whole are well written. The printing is clear and the paper and binding excellent. A few trivial misprints were noted, among which were four cases of the value for the diffusion constant (D) in the last article being given in terms of 10^7 instead of 10^{-7} . The volume contains comprehensive author and subject indexes; the entries in the latter were compiled using the recently adopted rules of carbohydrate nomenclature², but the articles to which they refer were written before these rules came into force. There is, however, no confusion.

To sum up, the volume is a valuable contribution to the literature and should be in the possession of all who are interested in carbohydrate chemistry.

CHEMICAL TECHNOLOGY

Encyclopedia of Chemical Technology

Edited by Raymond E. Kirk and Donald F. Othmer. Vol. 4. Cineole to Dextrose; pp. xvi+969. (1949.) Vol. 5. Di- to Explosions; pp. xvi+992. (1950.) Vol. 6. Explosives to Furfural; pp. xvi+1008. (1951.) Vol. 7. Furnaces to Iolite; pp. xvi+982. (1951.) Vol. 8. Ion Exchange to Metal Plating; pp. xvi+944. (1952.) Vol. 9. Metal Surface Treatment to Penicillin; pp. xvi+944. (1952.) Vol. 10. Pentacene to Polymethine Dyes; pp. xvi+976. (1953.) (New York and London: Interscience Publishers, Inc.) 25 dollars or £8 15s. each volume.

A HUNDRED years ago, the chief source of information bearing on chemical technology was Dr. Ure's "Dictionary of Arts, Manufactures and Mines". At the turn of the century Watt's "Dictionary of Chemistry" was available, but for general reference there was not much else. Thorpe's "Dictionary of Applied Chemistry" and Ullmann's "Enzyklopädie der Technischen Chemie" came into use later. The first volume of Thorpe's "Dictionary" had, however, appeared in 1890.

Turning over the pages of Kirk and Othmer's "Encyclopedia of Chemical Technology", of which Vols. 1-10 have now appeared, the tremendous progress of chemical technology during the past fifty

years is strikingly demonstrated. Already there are ten thousand pages up to the letter P, and more is yet to come. The subjects included in this encyclopaedia confirm the statement which is often made that chemistry nourishes the growth of all technology. One only needs to cite at random a few of the headings to separate articles to illustrate this statement—lubrication, furnaces, malaria chemotherapy, metallic coatings, lamp manufacture, eggs. There are, of course, many articles relating to the different branches of chemical industry—fuels, glass, fermentation, explosives and so on. Articles also are to be found on the techniques—instrumentation, electronics, gas analysis, mass spectroscopy and many other such subjects. The various processes proper to chemical engineering—drying, distillation, crystallization, mixing—are treated in an up-to-date way with suitable photographs and diagrams of plant. There will be found articles on different physical and physical-chemical subjects, such as heat transfer, diffusion, dialysis, electrochemistry, etc., which underlie chemical processes and chemical engineering methods. Besides all this, information is provided about individual chemical substances (organic and inorganic), their properties, their use, their methods of preparation or manufacture and the economic aspects relating to their supply. Pharmaceutical products, biochemical preparations, dyes and intermediates (more than a hundred pages), etc., are included. The article dealing with cosmetics, because of the wide variety of products, is even larger than that on iron; the section of the latter dealing with the blast furnace is perhaps rather too compressed, considering the scale of production with which the blast furnace is concerned. By the careful cross-referencing and the grouping of classes of compounds together, for example, hydrocarbons, petroleum products, cyanides, etc., it has been possible for the editors to provide much information without too much repetition and elaboration.

The articles are written by specialists, and the editors have taken trouble to maintain as uniform a treatment as possible and a high standard. Each article is followed by a brief bibliography. The presentation and printing are pleasing. Most of the contributors are working in the United States; many are widely known for their work throughout the world. The information collected in these volumes is a record of the state of chemical technology in the New World rather than the Old, and this is exemplified on turning up the sections on gas—natural gas, manufactured gas and carbonization: manufactured gas has greater relative importance in Britain than in America, and the technology is somewhat different.

The proportion of the world's trade in chemicals at the present time is nearly as great in the United States as in the whole of the rest of the world, and the turnover has increased at a much greater rate in recent years than in Britain; the rate of increase is greater also in Switzerland. The installation of refineries in Britain and development of other processes may help to widen the basis of chemical industry in this country. Nevertheless, it is comforting that penicillin, polythene and paludrin, to mention three new products under the letter 'P' alone, have their origin in British laboratories.

There are useful articles on such subjects as literature, nomenclature, dimensional analysis, presentation of data, chemical economics, etc. In the remarkably complete article on chemical literature,

there is, however, little mention of the importance of literary style, though in this respect the articles in the encyclopaedia are commendably well presented. The use of unnecessary technical terms is always a temptation, and an expression such as "the armamentarium of gas analysis" is not very elegant. I have found few misprints and few mistakes. In so large a field to be covered there are sure to be faults to find; thus one could grumble over a quotation from a paper to which reference is made in the article on hydrogen peroxide. But, among so much which is good and useful, to cavil is misplaced.

There is no doubt that this extensive and valuable encyclopaedia will find place on the shelves of many laboratories in spite of its bulk and its considerable cost. It will be valuable to the general reader who wants to widen his knowledge, for the articles are readable and informative, and to the specialist it will also be valuable as a work of reference, particularly if it is kept up to date by the issue of supplementary volumes. The specialist will, of course, find much which is omitted and perhaps much to criticize, but the attempt to present in this encyclopaedia the state of contemporary knowledge in all that pertains to chemical technology is certainly an ambitious one; in my opinion it is on the whole successful.

ALFRED C. EGERTON

HOUSE PAINTINGS IN ANGOLA

Subsídios Para a História, Arqueologia e Etnografia dos Povos da Lunda

(Museu do Dundo, Publicações Culturais No. 18.)
Por José Redinha. Pp. 32+55 plates. (Lisboa: Companhia de Diamantes de Angola, 1953.)

RESEARCH work on the archaeology and ethnology of the province of Lunda (Angola) in connexion with the Museum at Dundo is subsidized by the cultural department of the Belgian diamond company in Angola—Companhia de Diamantes de Angola. As a result, a number of splendid monographs have already appeared, dealing with various matters of interest in the area. The present volume is compiled by the curator of the Dundo Museum, Dr. José Redinha, and is concerned with paintings made by the natives on the clay walls of their houses, both inside and out, during the dry season of the year, June–September. The external paintings, at any rate, are completely destroyed during the rainy season. Except for a short explanation in Portuguese and a map, the volume is entirely devoted to coloured illustrations of the paintings. They are of very great interest to all students of art in the southern half of Africa. They do not recall the true bushman or pre-bushman art groups, but there is a feeling of similarity with some of the later art manifestations farther south. It is true that geometric design predominates in Lunda, but figures of animals and humans occur, and some of these are not unlike some of those found not so far away on rocks in south-west Africa.

There is no doubt that the Bantu have artistic ability. Canon Paterson, of Cyrene College, sent me some time ago a number of paintings made by Bantu children at the College, which he claims are free from European influence. They recall many to be found illustrated in the volume under review. Of course, the modern Bantu see things their forerunners never dreamed of—there is a delightful stylized picture of

a motor-car from a site near the River Chiumbe. But it does appear from Canon Paterson's evidence and now from the Lunda examples that the modern folk make elaborate paintings either on drawing paper or on the clay walls of their houses without having been taught by Europeans. The human beings sometimes appear in a very stylized manner, recalling those found in rock-shelters in southern Spain and dating there to the Copper Age. But there is no need to try to suggest any connexion because such conventionalizations of the human form occur in many places and are of many different dates; they occur, too, on the walls of rock-shelters in the New World.

The Diamond Company of Angola is to be congratulated on the time, trouble and money it devotes to archaeological and ethnological research. The present volume is a notable contribution to knowledge and, incidentally, is a delightful picture-book for one's study.

M. C. BURKITT

DISPERSAL PROCESSES IN FUNGI

Dispersal In Fungi

By C. T. Ingold. Pp. viii + 197 + 8 plates. (London: Oxford University Press, 1953.) 18s. net.

THE enormous fecundity of the fungi has long been known by those whose business it is to protect crops from attack by pathogenic fungi, or to prevent spoilage of stored materials by moulds and decay of timber by wood-rotting fungi. It is evident, too, to those who grow micro-organisms in pure culture on a laboratory or industrial scale. More recently its importance has been appreciated for another reason, for air-borne fungus spores have been identified as respiratory allergens, and in Great Britain the bulk of the microscopic dust particles suspended in outdoor air in summer seems to be either fungus spores or pollens. Bacteria also occur in outdoor air; but, as Pierre Miquel found seventy years ago, they are usually much less numerous than fungus spores—mainly because, unlike bacteria, the fungi have evolved a weird variety of mechanisms which propel their spores into the air. Other adaptations serve to aid their dispersal by animals, especially insects, and by water.

In this little book, which is addressed "to all those concerned with fungi as living organisms", Prof. Ingold lucidly describes the processes of fungus dispersal. It will be valued not only by the more academic biologists and by students with examinations to pass, but also will be a mine of information to those with a practical interest in the way fungi get into places where they are not wanted.

After a brief introductory survey, the remainder of the first-half of the book is taken up with a full account of spore liberation. Some of this material has been used in the author's well-known book on "Spore Discharge in Land Plants", and about a fifth of the excellent text-figures are from the same source. The new book, however, is in no sense a second edition of the earlier one. Dispersal processes after liberation are surveyed in the light of the rapid developments of the past dozen years. The processes of liberation accomplish only part of the dispersal process, and when discharged from its parent fungus body, the spore is transported to a greater or, more commonly, shorter distance by external agencies.

These are considered in the last half of the book in separate chapters on spores in the air, dispersal by insects, dispersal by larger animals; and there is a short chapter on seed-borne fungi. Not only is the literature surveyed in a stimulating manner, but also Prof. Ingold contributes original observations on nearly all these topics, especially in the final chapter on water as an agent in the dispersal of spores. Much still remains to be done, and, as he reminds us, many of the dispersal processes are still obscure. There are a bibliography of about 140 references and eight beautiful plates.

P. H. GREGORY

A SCIENTIST IN THE WORLD OF ART

Aesthetics and the Gestalt

A Collection of Essays and Other Writings. By Ian Rawlins. Pp. xi + 228 + 10 plates. (Edinburgh and London: Thomas Nelson and Sons, Ltd., 1953.) 18s. net.

THERE is nowadays a considerable number of scientists who are deeply interested in some or other of the arts, although the epoch of distinguished practitioners in both sides of the intellectual world is long past, perhaps since Leonardo da Vinci. Mr. Ian Rawlins is one of the far smaller minority who, officially trained in science, are able to indulge artistic interests to the extent of actual employment therein. He would not claim to be a creative artist, but he must allow us to recognize that he has a very weighty influence upon the arts; this influence he has exerted in two distinct ways, first as scientific adviser to the National Gallery and consultant on all questions of the safe keeping and material investigation of pictures, and secondly as a thinker and writer in the borderlines of general philosophy and aesthetics.

It is in this latter capacity that the reader meets him in this pleasant and often profound collection of essays. The principal adverse criticism might well be that the title is stupidly repellent: only a narrow range of British readers in science or art will be attracted by the word 'aesthetic', still fewer by 'gestalt'. Continental philosophical jargon causes English-speaking readers, even those concerned in the topics, to bristle like a dog, and it would be well to erase 'gestalt' from the dictionary as ruthlessly as most of us would erase 'existentialism'.

The little essays themselves belie that suggestion of self-conscious intellectualism. They are neat in thought and eminently readable, and even scientists who have thought the arts closed to them will find much to enjoy here. The pages range from a quantitative account of the atmospheric pollution of art galleries, through topics such as geometric theories of aesthetic appreciation, to historical problems from ancient Greece to modern Cambridge. Many are reviews which have appeared in *Nature*. After some cases, recently, of rather Victorian anti-religion in some scientific quarters, it is worth noticing how many of Mr. Rawlins's essays reveal a mind devoutly aware that there are aspects of experience needing other than scientific categories for their description. This is to be expected from someone who has escaped the narrowness of literary and material culture by opening a receptive mind to both.

MARTIN JOHNSON

Gem Testing

By B. W. Anderson. Fifth edition. Pp. 268. (London: Heywood and Co., Ltd., 1951.) 21s. net.

THE author, as director of the London Chamber of Commerce Precious Stone Laboratory, has unique experience in gem testing. That five editions of this book have been called for in ten years shows that it has filled a need both of the scientifically untrained jeweller, to whom it was originally addressed, and of the more advanced student.

Because of the value of the material, routine gem-testing must be non-destructive and is limited to physical methods. About half the text is devoted to their careful description and explanation. The basic physical properties, refractive index and specific gravity, serve to distinguish most of the natural gem species, although their determination is often made difficult by the mounting of the stone or limitations of the apparatus—for example, in the measurement of high refractive indices. A most useful additional property in such cases may be the absorption spectrum. Its use has been pioneered by the author to the extent that it now ranks as the key method in a number of cases. In this book is the only adequate description known to the reviewer.

With certain exceptions all these methods fail in that most important aspect of gem-testing, the distinction between natural stones and their synthetic, as opposed to imitation, counterparts, and the microscope becomes the *pièce de résistance*. Its use for this purpose is fully explained, and of the sixty-two text figures nearly half are photomicrographs; these are excellent in quality and selection.

The latter half of the text covers the identification of, and distinction between, all the principal gemstones, including those of organic origin such as pearl and amber. In this, as in the first section, useful hints and examples abound. There are also an alphabetical summary of properties in tabular form, a glossary, tables of specific gravity and refractive index, and suggestions for further reading. Despite its superficial simplicity, this is an authoritative work, well produced in clear type.

G. F. C.

Geography from the Air

By F. Walker. Pp. vii+111+96 plates. (London: Methuen and Co., Ltd.; New York: E. P. Dutton and Co., Inc., 1953.) 30s. net.

THIS book provides a useful introduction to the correlation of geographical data with the air photographs from which maps are finally constructed. Such a technique is most favoured in undeveloped countries where information is otherwise not rapidly obtainable; but in Great Britain, the only source tapped by the author, many geographical and ecological features have been made or modified by man, and excellent maps prepared by more pedestrian methods exist. It would be desirable to include and discuss examples—which are certainly available from the British Dominions and Colonies—of untouched virgin country in diverse geographical, geological and climatic provinces; and to consider the uses of oblique photography, monochromatic filters, the habits of vegetation growing under natural control, and weathering action differing from that of the British Isles.

As regards details: it is not necessarily true (p. 11) that geological facts evident on air photographs are equally well observed on the ground, nor (p. 1) that there is no vertical scale distortion in a

stereo-pair—it can be troublesome over mountainous country. Reference to the page-numbers of the text-descriptions ought to be made on the plates, only three of the ninety-six embodying pairs for viewing with a pocket stereoscope. Since the main force of the technique lies in the three-dimensional appreciation, the inclusion of more of such pairs would be preferred, though the effect of the process screen is disturbing. Plate 37 (p. 1 of text) should be Plate 38.

In recognizing that examples from overseas are lacking and that archaeology and photogeology have received but scant attention, the author has disarmed criticism, for the subject is expertly handled within the limits chosen; but it is worthy of a wider range of treatment. This would be welcome in a later edition, which might well include a selected bibliography.

D. W. BISHOPP

Ants

By Derek Wragge Morley. (New Naturalist Series.) Pp. xii+179+15 plates. (London: William Collins, Sons and Co., Ltd., 1953.) 18s. net.

THE pleasantly discursive story of the author's own observations on the habits of ants, in Chapter 1, might have formed the happy beginning of a book for the non-technical reader with an interest in natural objects; the notes on the various species and the illustrated key, though not free from defects, could serve the same purpose. But as a scientific monograph that is said to give "a clear and excellent summary of the knowledge of these fascinating creatures", this book is scarcely a success. There is little of moment that cannot be found in Donisthorpe, Wheeler and nineteenth-century authors; the book lacks coherence and precision; and some of the truly fascinating aspects of ant biology, such as the structure and development of the colony and the determination of the castes, are virtually omitted (except for some details of mixed colonies). The chapters on anatomy are heavily weighted with details that are of interest principally in systematic work: in many cases the terminology is old-fashioned (for example, "chitin" for 'cuticle', p. 33; "bourrelet glands", p. 124), and there are a number of odd mistakes (for example, "mesonotal sternite", Fig. 5). The growth of ants is dismissed with extreme brevity; the distribution maps, given for every species, are often incomplete (for example, *Monomorium pharaonis*, which now has a respectable Scottish literature, is shown nowhere north of Essex). Some of the photographs, however, are excellent; it is a pity that the text is scarcely of the same standard.

J. A. DOWNES

Chemistry of Carbon Compounds

A Modern Comprehensive Treatise. Edited by Dr. E. H. Rodd. Vol. 1, Part B: Aliphatic Compounds. Pp. xvii+779+1462. (New York and Amsterdam: Elsevier Publishing Co., Inc.; London: Cleaver-Hume Press, Ltd., 1952.) £5 15s.

THE second part of Vol. 1 of this work carries on the discussion of the aliphatic series begun in the first (reviewed in *Nature*, 170, 508; 1952) and deals with the more complex (and therefore more interesting) compounds of this type. After a description of the hydroxy-, amino-, aldehydo-, keto- and poly-carboxylic acids, there follows a series of chapters on the carbohydrates and their multitudinous derivatives. Authoritative coverage of this latter topic has been ensured by the expert knowledge of

Dr. J. K. N. Jones and the late Dr. E. G. V. Percival; the full and detailed treatment renders this section a very valuable source of modern information for the carbohydrate chemist. The volume ends with chapters on the proteins and the enzymes which supply the scaffolding of the modern ideas concerning these vital substances together with ample references for further detailed study.

The characteristic of the work developed in the first volume—that is, the ready availability of up-to-date leading references—is well maintained in the second part of this important compendium.

Physical Chemistry made Plain

An Aid for Intermediate Students and Others. By J. H. Mandleberg. Pp. viii+287. (London: Cleaver-Hume Press, Ltd., 1952.) 15s. net.

THE author, an industrial chemist, calls himself "a chronic and incurable non-mathematician". His purpose is to teach physical chemistry, at post-matriculation level, mainly through numerical examples, and he thereby hopes to promote its study "by removing some of its terrors". The material is divided into seventeen chapters. The author's method is to recount the general principles of the subject under treatment, to work out several illustrative numerical examples in considerable detail, making the procedures abundantly clear, and to add many more for the student to solve; answers are given to all the problems.

Great pains have been taken to meet the needs of less able students, and in this respect the work is exceedingly well done. Still, understanding comes to many a student only when he sees the graph drawn of the problem in question; yet, there is neither graph, labelled diagram nor line-illustration in the book. Moreover, I find but little support for the claim that "an attractive feature is the frequency with which the student is reminded of the relevance of his work to industrial processes". The author gives brief mention of some principles not susceptible of quantitative treatment at this level, but others he omits. The preface calls this book a "review of physical chemistry": it would be preferable to call it a book of chemical calculations. G. FOWLES

Thermal Diffusion In Gases

By K. E. Grew and T. L. Ibbs. (Cambridge Monographs on Physics.) Pp. xi+143. (Cambridge: At the University Press, 1952.) 22s. 6d. net.

THERMAL diffusion in gases was predicted theoretically long before it was observed experimentally, and it is only during recent years that the consequences and importance of this effect have been fully developed. The immense stimulus given to the study of thermal diffusion and related phenomena by the utilization of this method for the separation of isotopes and gas mixtures resulted in a considerable output of experimental work. The publication of this monograph, which summarizes these developments, will be especially welcomed.

The emphasis in the monograph is largely on the experimental aspects, and Chapters 1-5 consist of an introduction to the theory of diffusion in gases, an account of the experimental methods and results, and the correlation of results with theory. In Chapter 7 the related phenomenon, the diffusion thermo effect—that is, the setting-up of a transient temperature gradient when one gas diffuses into another initially at the same temperature—is discussed from both the theoretical and experimental

aspects. The remaining Chapters 7 and 8 describe the application of thermal diffusion to the separation of the components of gas mixtures and thermal diffusion in the liquid phase, respectively.

This is the only book of its kind containing both a comprehensive survey of the experimental field and a careful and clear exposition of the underlying theory. The book is well written and excellently produced, and it can be recommended to all interested in this subject.

Photoconductivity In the Elements

By Dr. Trevor Simpson Moos. Pp. x+263. (London: Butterworths Scientific Publications, Ltd., 1952.) 50s. net.

PHOTOCONDUCTIVITY is a subject which claims attention on two grounds: it provides a useful tool for examining certain aspects of the nature of the solid state and it has useful practical applications. Photoconductive materials have been studied intensively during the past few years, and this up-to-date book by Dr. T. S. Moos is therefore to be welcomed.

The book is divided into two parts. Part 1 is concerned with theoretical aspects of the properties of photoconductors. The treatment is clear, but the reader is assumed to have the background of, say, a physics graduate; those without this background will, however, be helped considerably by the numerous references given in the text. Part 2 gives a detailed review of experimental studies of the properties of certain photoconductive materials; photoconductive compounds are not included in this review, which is confined to the elements boron, carbon (diamond), silicon, germanium, grey tin, phosphorus, arsenic, antimony, sulphur, selenium, tellurium and iodine.

As a whole, the book is concise and well written; it provides a useful, if somewhat limited, survey of an important subject. A. H.

Dynamical Oceanography

By Prof. J. Proudman. Pp. xii+409. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1953.) 55s. net.

THIS book covers most of the principles of hydrodynamics that have application to oceanography. The author has a genius for concentrating on the central features of a problem. In a large part of the book the problem is not to solve the hydrodynamical equations, but to show how much can be derived from a few simple properties without actually solving them in detail. In the application to mean conditions, and therefore to steady states, a great deal can be done from continuity of mass and quantity of salt and the circulation theorem, particularly toward estimation of currents far from land. Turbulence and mixing are treated in some detail. Variation of conditions with time appears first in these chapters, in which estimates of eddy-viscosity appear. The rest of the book deals with tides, seiches and waves. The treatment has been deliberately confined to the simpler problems, and little is said about the formidable ones on tides in the open ocean that have been solved by the author and his colleagues.

Quantitative applications appear at many points, with checks against observation whenever these are available. The agreement is in some cases astonishing—for example, the calculation of co-tidal lines for some narrow regions with complicated boundaries, such as the English Channel. HAROLD JEFFREYS

THE MEDICAL RESEARCH COUNCIL LINEAR ACCELERATOR AND CYCLOTRON

By CONSTANCE A. P. WOOD and G. R. NEWBERY

A NEW building (see Fig. 1) has recently been completed for the Medical Research Council at Hammar Smith Hospital, London. This building houses two large machines for the acceleration of atomic particles. Installed in the south end of the building is an 8-MeV. travelling-wave linear electron accelerator; this machine has been designed specifically for X-ray therapy and is already in daily use for the treatment of patients. At the north end of the building, a 45-in. cyclotron is under construction. The central portion of the building consists of research laboratories on the upper floors and clinical rooms for patients on the ground floor.

The linear accelerator is installed in a treatment room (see Fig. 2) which is surrounded by walls of concrete four to six feet in thickness. There is no door to the treatment room; but easy access is afforded by means of an indirect corridor with concrete walls on either side. The protection thus afforded is much greater than is necessary simply for the safety of personnel; it is sufficient to enable work to be carried out in the adjacent research laboratories involving the measurement of minute quantities of radioactive material with Geiger counters and high-pressure ionization chambers. The radiation level at the control desk is less than one-hundredth of the recognized tolerance value. The

Fig. 2. Treatment room

Fig. 1. Building for the Medical Research Council linear accelerator (right) and cyclotron (left)

operator at this control desk can see the patient under treatment by means of a periscope system of mirrors viewed through an air tunnel in the concrete wall.

The technical details of the 8-MeV. linear accelerator have already been described by Miller¹. The accelerating tube is three metres in length; it is suspended from the ceiling, thus leaving the floor of the treatment room clear. The 8-MeV. electron beam passes out of the end of the accelerating tube into a rotatable X-ray head. In this, an electromagnet bends the electron beam through a right-angle before it strikes the gold transmission target to produce the beam of X-rays. The X-ray beam is then collimated to a maximum diameter of 28 cm. at 1 metre from the target by passing it through a conical hole in a series of tungsten-copper alloy blocks. The final dimensions of the X-ray beam can be controlled by means of an adjustable diaphragm system consisting of four 3-in. thick tungsten-copper alloy blocks moving in two interlocked pairs in a single plane. Thus any size of treatment field can be obtained, from 4 cm. to 20 cm. square, or any intermediate rectangle. Scales are provided for setting the size of the field, and circular fields can also be obtained by suitable inserts of tungsten alloy. The target-to-skin distance usually employed in treatment is 1 metre.

A lamp and mirror are provided to illuminate the treatment area on the patient's skin. In addition, front and back pointers on the X-ray head indicate the points of entry and exit of the central axis of the X-ray beam on the patient's skin. The dose-rate and the total dose administered in any one treatment are measured by ionization chambers built into the head of the machine and connected to d.c. amplifiers.

By rotation of the X-ray head, the X-ray beam can be directed accurately into the patient at any desired angle. To enable the patient to be brought into position in the X-ray beam, the whole floor of the treatment room can travel vertically up and down over a distance of 5 ft., and in addition a specially designed treatment couch can travel horizontally across the moving floor. The angular motion of the X-ray beam, the vertical movement of the floor and the horizontal movement of the couch can be automatically co-ordinated by an electronic servo system enabling the patient to be moved in an arc around the machine. As a result, once the entry point of the beam (marked by the front pointer) has been set correctly on the patient's skin, it is possible to adjust the angle of the beam until the exit point (as shown by the back pointer) is also correct, without ever altering the entry point. By this arrangement patients can be set up for treatment on this machine with greater accuracy and speed than is possible with the conventional type of X-ray equipment.

The high intensity output of the linear accelerator, 100–200 rads per minute (1 rad = 100 ergs per gm.) at a metre, is of great value in the treatment of patients, since the time of each treatment is thereby reduced to about two minutes. The initial large expense of the machine is thus to a great extent offset by the much larger number of patients who can receive treatment in a given time.

The control desk of the machine is simple and can be operated in the usual way by radiographers. The required dose can be set in steps of 10 rads up to a maximum of 600 rads; the machine switches itself off automatically when the prescribed dose has been administered.

There are, for the first time, incorporated in this one machine all the facilities needed to permit the full exploitation of the technical advantages to be gained by using very-high-energy X-rays in the treatment of malignant disease. It makes possible the delivery of an adequate dose to a deep-seated tumour of highly penetrating 8-MeV. X-rays collimated into a well-defined, high-intensity beam, which can be conveniently and accurately directed into the patient at any angle.

In Fig. 3 a comparison is made of the penetration of X-rays produced at 8 MeV., at 2 MeV. (approximately equivalent to radiation from a 1,000-curie cobalt source) and the conventional 200-kV. X-rays; the greatly increased penetration obtained at 8 MeV. is clearly shown. This figure also illustrates the build-up of intensity below the skin at 2 and at 8 MeV. This build-up, which occurs with supervoltage radiation, is due to the fact that the secondary electrons, which produce most of the ionization, are projected mainly in the direction of the incident beam and have a range which increases with the voltage. In the case of the 2-MeV. X-ray machine and the cobalt unit, the maximum dose is at 0.5 cm. depth, whereas this occurs at a depth of 2.0 cm. with 8-MeV. X-rays. This build-up of intensity below the skin and the high penetration of the X-rays produced by the 8-MeV. linear accelerator make

Fig. 3. Comparison of central axis depth doses for a 10 cm. x 10 cm. X-ray field, 200 kV., 2 MeV., and 8 MeV. in a water phantom.

possible the delivery of an adequate dose to a deep-seated tumour without any damage to the overlying skin.

At one time it was thought possible that supervoltage X-rays might have a different biological effect from 200-kV. X-rays. A clinical experiment was therefore carried out at the Radiotherapeutic Research Unit of the Medical Research Council to compare the biological effect of 200-kV. X-rays and a radium beam which is equivalent to 2-MeV. X-rays¹. As a result of this experiment, it was concluded that the great advantage to be expected from the use of supervoltage therapy was not in any different biological effect but only in the enormously improved dosage distribution which can be obtained by this means. Experimental biological work has since re-emphasized the fact that there is no great difference in biological efficiency between 200-kV. X-rays and those generated at much higher voltages.

To what extent this improved dosage distribution may increase the rate of cure in the radiation treatment of malignant disease only a prolonged clinical trial can determine. One advantage which is certain is that it will be possible to treat patients with a much greater degree of comfort. The reduction of skin reaction itself is of great value in X-ray therapy, and it can also be safely assumed that the lower absorption of energy in bone as compared with soft tissue, which occurs in supervoltage X-ray therapy, will lessen the risk of bone necrosis and so contribute to the success of treatment.

The 45-in. cyclotron, weighing some 180 tons, is still under construction; this machine is housed at the north end of the building in a large concrete room with ceiling and walls from six to ten feet in thickness. The room has two close-fitting sliding concrete doors weighing 35 and 190 tons. The cyclotron will be operated from a remote-control room.

The beam of fast neutrons which can be produced by the cyclotron will enable investigations to be carried out to determine the effect of neutrons on living and inert matter. There is no question of the efficiency of neutrons in destroying malignant cells. What is not known is whether this property can be

turned to advantage over other forms of radiotherapy in the treatment of malignant disease in patients.

Another use of the cyclotron lies in its ability to produce certain radioactive isotopes which cannot be produced in the atomic pile. The particular importance of this cyclotron lies in its ability to produce in a hospital certain isotopes which, on account of their very short life, must be used immediately they are produced. Facilities have been provided adjacent to the machine for this purpose.

DEXTRAN AND ITS APPLICATIONS

ON the evening of December 3 the Microbiology Group of the Society of Chemical Industry held a meeting in the hall of the Medical Society of London, 11 Chandos Street, London, W.1, presided over by Dr. L. A. Allen, at which various applications of dextran were discussed.

Prof. M. Stacey introduced the subject with a paper on "Polyglucose Structures with Special Reference to the Dextran Group". He commented on early work in Sweden and in Birmingham, saying that the dextran polysaccharides have achieved an important medical use as blood plasma substitutes or blood volume expanders, and their derivatives are possible anticoagulants. Since they can readily be produced from cane or beet sugar by fermentation methods on an industrial scale, other uses, such as colloids of precise size and shape, will doubtless be found for them.

Chemical and physical methods of carbohydrate chemistry are now so well developed and of such diversity that we can now determine with great accuracy the homogeneity, size, shape and molecular structure of most polysaccharides. Homogeneity can be determined by physical techniques such as measurements of optical rotation, electrophoresis, ultracentrifugal properties, diffusion, scattering of light, and immunochemical studies, all of which also give information on molecular size and shapes. Constituent units can be determined by hydrolysis with acids followed by paper and column chromatography, ionophoresis, etc., while acetylation, methylation, periodic oxidation, infra-red studies, ionophoresis, etc., pick out the nature of ends of chains, repeating units, types of linkage and structures generally. Number average and weight average can all be determined by classical methods for dealing with macromolecules; for example, the physical methods already mentioned, viscosity measurements, and methods involving reaction at reducing-chain ends such as copper number measurements and the addition of labelled hydrogen cyanide.

Almost every type of polyglucose structure is now known where the glucose units are in the pyranose form. In starch the amylose component is a chain of at least two hundred glucose units joined by (1 → 4)- α -linkages, while the ramified amylopectin has short chains of twenty glucose units joined as in amylose but cross-linked by (1 → 6) linkages. Glycogen consists of shorter chains with (1 → 4)- α -linkages and (1 → 6) cross-linkages. Cellulose is entirely linear with very long chains of probably a thousand

glucose units linked in the (1 → 4)- β manner. The polyglucose made by the crown gall micro-organism possesses mainly (1 → 2) linkages, while the yeast 'glucan' has mainly (1 → 3) linkages. *Nigeran* from *Aspergillus niger* has alternating (1 → 4) and (1 → 3)- α -linkages, and luteose from *Penicillium cubal* has a long glucosan chain with (1 → 6)- β -linkages.

The predominating linkage in the dextrans is the (1 → 6)- α -linkage, but a variety of types is known varying from completely linear structures to highly ramified types with additional (1 → 4)- α - and (1 → 3)- α -cross-linkages and combinations thereof. All are macromolecules with molecular weights of the order of millions. Great interest arises in methods for degrading the dextrans and in separating and selecting homogeneous fractions for infusion purposes. Breakdown can be effected by acidic, alkaline, enzymic and oxidative hydrolysis, or by ultrasonic or thermal treatment. Fractionation precipitation techniques, using mainly organic solvents and aqueous solutions, not only separate large and small molecules but will also pick out linear from branched chains—the infra-red technique being useful for rapid control of fractionation.

Recently, it has become possible to control the enzymic synthesis of polyglucose molecules and indeed to grow them to size. Great advances have been made in the enzymic synthesis of starch and glycogen. For these, phosphorylase acts upon glucose-1-phosphate to give the straight-chain amylose. This may then be acted upon by the branching 'Q-enzyme', which effects chain-shortening by breaking about one in every twenty (1 → 4)- α -linkages and which then re-forms the molecule by creating (1 → 6) cross-linkages giving the highly laminated structures of glycogen and amylopectin. This 'transglycosylase action' is responsible for synthesizing the highly branched dextrans, for at least two enzymes seem to be involved: a (1 → 6)- α -linked straight-chain former and a transglycosylase which forms (1 → 4) and/or (1 → 3) linkages.

For polysaccharide synthesis generally three factors are needed: enzyme, specific substrate and receptor molecule. For dextran synthesis by *Leuconostoc* species, sucrose is a highly specific substrate, and preformed dextran forms the receptor molecule or 'primer'. When a small number of large dextran molecules is used to prime the reaction, macromolecules of very large size result. When a relatively large number of small dextran molecules is used to provide receptor groups for synthesis from non-reducing chain ends, they are all lengthened to the same extent, and relatively small dextran molecules result. Thus, it is now possible actually to grow dextran 'to size'—for example, to molecular weights of seventy thousand for infusion purposes. The method uses the living cell, whereas American workers are studying similar polymerizations with isolated enzyme systems.

Mr. A. E. James then presented a paper on "The Technology of Dextran Production", showing that the production of dextran for use as a plasma volume expander may be divided into five main stages: fermentation, degradation, fractionation, purification and final testing after bottling. Dextran is produced as a large macromolecule during the fermentation of sucrose by a selected strain of *Leuconostoc mesenteroides*, although the use of the dextran 'sucrase' enzyme has been reported in the United States. The dextrans produced by different organisms vary from almost linear to highly branched molecules. The

reduction of the molecular size of the native dextran to approximately that of the blood proteins may be achieved by several degradative steps such as acid or alkaline hydrolysis, thermal or pyrolytic breakdown, irradiation with ultrasonic vibrations or enzymic breakdown. Recent work has indicated the possibility of direct synthesis of the required molecular weight, thus avoiding degradation.

The material from degradation is very poly-disperse, and the objectionable larger molecules and the useless small ones have to be removed by selective precipitation. Acetone and the lower alcohols have been used as precipitating agents. This process does not yield a homogeneous dextran with respect to molecular weight, and the commercially available transfusion solutions contain a range of molecular sizes dictated partly by medical requirements and partly by economic considerations. Ultrasonic degradation appears to be unique, as it yields a product requiring virtually no fractionation to yield a satisfactory medical preparation.

The desired fraction of dextran is freed from precipitants, pyrogen, ionic impurities and colour by selective adsorption and ion-exchange, and may then be filled directly as a solution in water, sodium chloride solution or glucose solution. Alternatively, it may be spray-dried for bulk testing and distribution. After bottling, rigorous chemical bacteriological and pharmacological tests are applied.

Dr. F. Fletcher followed with a discussion of the "Properties of Dextran from the Physiological Aspect". He pointed out that the maintenance of a normal blood volume depends on the hydrostatic pressure of the capillary blood and the colloidal osmotic pressure gradient between the plasma and tissue protein. Plasma contains albumin, globulin and fibrinogen; but it is the albumin fraction (55 per cent of total protein) of molecular weight about seventy thousand which mainly contributes to the colloidal osmotic pressure.

It is essential that any colloid intended as a replacement for plasma protein be retained in the blood vessels and not rapidly lost through the capillaries to the tissues or urine. The retained colloid must exert a colloidal osmotic pressure similar to that of the normal plasma protein. Dextran can be prepared to meet these criteria and is a satisfactory substitute for plasma protein.

Dextran fractions of various ranges of molecular weight have been studied, and the distribution and excretion-rates have been compared. The molecular-weight distribution of such fractions can be determined by ultracentrifuge, scattering of light, or techniques of the measurement of osmotic pressure, but it is more usual for measurements of intrinsic viscosity to be made. The relationship between intrinsic viscosity and molecular weight has been published by various workers.

The distribution of dextran in the body is influenced by its molecular-weight distribution. Relatively small molecules below a weight-average molecular weight of sixty thousand are excreted in the urine within a few hours after administration. Molecules slightly larger can also pass readily through the capillary walls into the tissue fluid, thus tending to reduce the effective osmotic pressure gradient. Therefore, on the basis of these physiological considerations, the higher molecular range of dextran used in Britain appears to be preferable for clinical use compared with dextran fractions of lower average molecular weight.

Prolonged storage of a non-physiological colloid in the body is undesirable. That dextran is metabolized in the body has been suggested by the finding of radioactive carbon dioxide in the expired air of animals receiving injections of dextran labelled with carbon-14, obtained by the *Leuconostoc* fermentation of radioactive sucrose. Structural differences exist between dextrans produced by different strains of *Leuconostoc mesenteroides*, and immunological studies on structurally different types of dextran might influence the type of material selected for clinical use.

Mr. A. W. Wilkinson continued the physiological discussion with a paper on "The Clinical Applications of Dextran". After paying a tribute to Prof. Stacey and other pioneer workers on dextran, he commented on its importance in blood studies, and went on to say that the cells of the living body are surrounded by an environment of extracellular fluid; at any moment this extracellular fluid may be arbitrarily divided into one quarter, which is within the blood vessels in the form of plasma, and three quarters, the interstitial fluid, which is outside the blood vessels in the immediate neighbourhood of the cells. This separation depends on a balance between the hydrostatic forces in the blood vessels and the interstitial space, and the osmotic pressure of the plasma proteins. In normal tissues flow in the capillaries is intermittent and depends chiefly on requirements related to tissue activity. After injury there is a very marked increase in capillary permeability in the injured tissues and the volume and protein content of interstitial fluid increases, this increase in volume being due to a greater turnover of fluid rather than to simple local accumulation, because lymph formation is also increased up to eight times. If the injury is large, so much fluid may be lost from the blood vessels that the volume of blood in active circulation may be reduced enough to cause reduction of the peripheral blood pressure and a state of 'shock'. Shock may also be caused by loss of whole blood. It is now recognized that, in shock, capillary permeability is increased only in the injured tissues.

The most satisfactory treatment of shock is by the early, rapid and complete replacement of lost blood or plasma by the transfusion of blood, plasma or a substitute for plasma, such as dextran. To be successful as such a replacement, the dextran must be fractionated so that as little as possible is lost in the urine or through the unusually permeable capillaries of the injured tissues and as much as possible remains within the vessels.

The effects of injecting a litre of a 6 per cent solution of dextran in 0.9 per cent saline have been studied in normal volunteers. There is an immediate reduction in packed cell volume and of total plasma protein and plasma albumin concentration. These changes afterwards slowly pass off, and the plasma dextran concentration, initially 1.1-1.5 gm./100 ml., falls slowly over 8-10 days to less than 0.1 gm./100 ml., but even at this time the packed cell volume remains below the original value. Detailed study of the changes during the first 24 hours after the infusion has shown that during the 2 hours or so following the initial increase in plasma volume, which varied from 0.3 to 1.3 litres, there is a reduction in plasma volume almost to the initial quantity. During this short period more than 40 per cent of the total quantity of plasma albumin in solution and nearly 40 per cent of the injected dextran leave the blood vessels. During the next 8-12 hours there is a gradual increase in plasma volume, and

the quantity of plasma albumin in circulation increases to that found immediately after the infusion stopped; but the increase in total circulating dextran is much less. After 24 hours only 8 per cent of the injected dextran has been recovered in the urine and 65-75 per cent remains in circulation within the vessels, so that about 20 per cent is untraced. The explanation of these changes seems to be that the acute overloading of the circulation produced by the rapid injection of this dextran solution is relieved by the loss of intravascular fluid into the interstitial space, with subsequent slow return over the next 8-12 hours. Similar results have been obtained in shocked patients, and two examples of the rapid and lasting improvement in blood pressure and clinical state were described.

All these volunteers exhibited 'reaction' which could be resolved into two phases, urticarial and vasomotor, that were separated in time. Whereas the urticarial phase may be due to the peculiar characteristics of the dextran used, the vasomotor phase seems to be related to the rapid shift of fluid from vessels to interstitial space.

Finally, Mr. A. R. Lockwood briefly reviewed "The Utilization of Dextran and some of its Derivatives". The current utilization of dextran in non-clinical applications depends largely upon the economic separation of the crude polysaccharide from the crude fermenter broths. Solvent precipitation is the only practical means so far employed, but is costly and must usually be followed by spray or roller drying. Some attention has been directed to using the whole fermenter broth—for example, in oil-well drilling muds and edible syrups. Sugar syrups made by the addition of sucrose to *Leuconostoc* pure cultures form an effective way of conveying dextran into a variety of food products without the problem of prior separation.

Derivatives of current interest include the sulphuric polyesters, which have a heparin-like blood anticoagulant action; some of them have been shown recently to be suitable for clinical use. The carboxymethyl ethers are likely to have superior stabilizing powers compared with the neutral polysaccharides. Other ethers and mixed ether/esters have been described, of which the most interesting is the polymerizable allyl derivative. Attention has been directed to the importance of microbial polysaccharides in soil structure; but the exploitation of dextran in this field may have to follow the development of large-scale, low-cost crude dextrans, possibly from the direct fermentation of natural sugar juices.

The discussion at the meeting was opened by Dr. C. R. Ricketts, who said that he thought dextran production might be regarded as the dextran industry now that there are six or eight factories engaged in it. He thought that the present phase of 'tailoring' the molecules of dextran after its initial preparation would be followed by direct production, by fermentation, of the molecular size and form required. The work on the effect of addition of short-chain dextrans and of sugars to the fermentation mixture in modifying the dextran produced provides a fruitful field for simplification in manufacture of the kind suggested and might have an important effect on making preparations for clinical use.

In reply to a question by Mr. D. Armstrong why dextran of a molecular weight of sixty thousand is excreted by the kidney whereas albumin of similar molecular weight presumably is not, Dr. Fletcher said that molecular shape is also important in

excretion and that albumin can be re-absorbed back from urine by the kidney whereas dextran cannot. Mr. A. L. Bacharach suggested that in practice this matter is approached empirically and is not based on purely physiological concepts. In commenting that Prof. Stacey's paper showed the advantages of ultrasonics in achieving uniformity of molecular size, Mr. H. F. Frost asked if this method is used commercially, and Mr. Lockwood replied that there has been difficulty in getting large ultrasonic units of suitable types but that they are now being employed. Dr. D. H. F. Clayson asked if the breakdown of dextran in the body is due to attack of the (1 → 6) linkages and, if so, could it be controlled by adding inhibitors such as amylase to the blood. Prof. Stacey replied that there is no knowledge yet on either of these points, for no enzymes which could break such linkages have been isolated from body fluids. An inquiry was made by Mr. H. J. Bunker as to the raw materials for the large-scale development of dextran to which Mr. Lockwood referred, and Prof. Stacey replied that any sugar material can be used, including dextrins, and that recent restrictions in production in the Jamaican sugar industry because of over-production suggest that even raw cane sugar might be available for the purpose. Cane sugar undoubtedly must be one of the most important raw materials of the future. Mr. J. Green asked Mr. Wilkinson what was his evidence for saying that the dextran should not have molecular weight above three hundred thousand for clinical use, and the latter said that above this value aggregation of red cells can be demonstrated and this is said to be undesirable; he thought that this tendency might well not be of great importance, since turbulence in the capillaries could be expected to overcome it.

THE SHIRLEY INSTITUTE

ANNUAL GENERAL MEETING

THE thirty-fourth annual general meeting of the British Cotton Industry Research Association was held at the Shirley Institute, Manchester, on December 10, 1953, under the presidency of the chairman of the Association, Mr. N. G. McCulloch. In his speech Mr. McCulloch referred particularly to the statutory levy that came into operation during 1953, as a result of which all cotton processors in Great Britain now contribute to the Institute and are eligible to take advantage of the services which the Institute offers. He hoped that all new members would take full advantage of this opportunity. Mr. McCulloch also emphasized that firms who process rayon and synthetic fibres are encouraged to continue in membership or become new members, since so much of the Institute's work is concerned with, or applicable to, these fibres as well as to cotton. The honorary treasurer of the Association, Mr. J. Lindley, also referred to the levy, and paid special tribute to the generous way in which the industry had responded to the appeal for funds which it had been necessary to make in order to tide the Institute over the period before the first collection of the levy.

Dr. F. C. Toy, director of research, presented his annual report and directed attention to the more important of the year's activities. He mentioned especially two essays in the educational field: the travelling exhibition of the Institute's work on sizing

and weaving, and a course of lectures on card-room planning which had been given at the Institute and attended by more than a hundred and fifty mill representatives. Dr. Toy referred to the importance of work proceeding on mixed fibres, particularly mixtures of natural and synthetic fibres such as cotton and nylon. All in all, he said, the year had been an exciting one, marked by advances on both the scientific and technological fronts.

In the laboratories, which were open for inspection after the meeting, many of the researches attracted particular attention. The most interesting exhibit for spinners was the 'Shirley opener', a machine which had already attracted considerable attention at the exhibition of textile machinery at Belle Vue, Manchester. Separating lint from trash aerodynamically, by the use of stream-line air flow, it saves space and time in the mill. For the more scientifically minded, an apparatus for examining stroboscopically the form of ballooning yarns on spinning machines and for measuring the tension was shown, as were various devices for following the movement of fibres during drafting and measuring the forces involved. In the experimental spinning-room there was further evidence of work designed to improve quality and productivity.

In the Weaving Department, the automatic size-box was on view. By the use of this device, which employs a new principle of control that is independent of such factors as the viscosity of the hot starch paste, or size, which is used for protecting the yarn in weaving, warp yarns can now be prepared for weaving in such a way that there is complete and automatic control, at the machine, of the amount of solid material applied to the yarn. The Institute has for many years concerned itself closely with the problem of finding sizes that give good performance in weaving and with analysing the effects of the lubrication and adhesion provided by the size ingredients, and more recently there has been particular emphasis on the relatively difficult problem of finding sizes for hydrophobic fibres such as nylon and 'Terylene'. A small-scale sizing equipment, in which all the variables are under control and on which small quantities of yarn can be sized rapidly, was shown.

The 'Shirley rayon loom', which has been designed to take account of all the physical and engineering knowledge that has been gained from researches into weaving and loom mechanisms over past years, could not be shown as it is still being developed in co-operation with a loom manufacturer. However, the separate mechanisms, some of which were also shown in the travelling weaving exhibition, were to be seen. These have been designed by physicists and engineers working together, and prototypes have been developed in the Engineering Department.

The staff of the Finishing Department were able to discuss with members their work on physical and chemical problems over a large field. The behaviour of pressure bowls during calendaring and mangling has been examined in a preliminary manner photographically, and, in the calender, more carefully and accurately by a photoelastic technique which has given interesting results. The experimental calender and mangle constructed in the engineering shop were shown. The chemical engineering section of the Department is interested in two main problems: drying, with the emphasis on convection and suction dryers; and fluid flow with particular reference to the dyeing of closely wound packages. The experimental equipment in a new and well-equipped

laboratory of this section was shown for the first time. Physicists and chemists shared in discussing with members the work on printing. The young science of rheology comes into its own in this branch of the textile industry, since the non-Newtonian materials used for printing on fabrics are used at a wide range of rates of shear. The chemists find great interest in the consideration of starches and gums used in printing pastes.

In the Rayon and Silk Departments two problems of great interest to the chemist are under consideration. In the Rayon Department, work has proceeded for some years on the fractionation of regenerated celluloses according to their molecular weight, using osmotic and viscometric methods for the determination of molecular weight, together with an ultra-centrifuge designed and built at the Institute. This work has now reached the interesting stage where the physical properties of fibres prepared from specific fractions are being examined. In the Silk Department, the recent rapid developments in paper chromatography have been of considerable help in the problem of elucidating protein structure, with particular reference to the main constituents of the silk fibres fibroin and sericin. The more chemically minded visitors also found plenty to interest them in the fundamental work of the Chemistry Department, where the particular interest for many years has been the light shed on the structure of cellulose by studies of its oxidation.

The Physics and Physical Testing Departments are now housed in the new building, completely occupied for the first time in April 1952; some members were still interested in the design of the building, and particularly in the disposal of services and the means adopted for ensuring controlled humidity and temperature throughout the laboratories. Many were interested in the activities of the Testing Department, for it is there that much of the work on quality control is carried out, and particularly in the design of instruments. It is there also that much of the programme on blended fibres will be done, since the accumulated knowledge on the structure and mechanics of textiles lies there. Much of the more fundamental work on the physical properties of textile materials is done in the Physics Department; but perhaps of greatest interest to visitors was the work on the 'barrier' properties of textiles. Textile materials are almost invariably used as a barrier to something; it may be to heat, light, sound, water, water vapour, etc. Much work has been done, and will continue to be done, on the production of textiles which allow the passage of water vapour but not of water. More recently work on the properties of textiles as a barrier to dirt has been started, and it is hoped that in time much information will be obtained on the mechanism of soiling. In the meantime, members showed interest in an apparatus which has been developed in the course of this work for the convenient and rapid measurement of atmospheric dirtiness. Not entirely dissociated from soiling is the topic of static electricity, its cause, formation and dissipation. This has been a subject of fundamental interest for some time, and the apparatus used was available for inspection.

Lastly, mention must be made of the work being done on the cotton fibre. In addition to the large amount of co-operative work with the Raw Cotton Commission, Empire Cotton Growing Corporation and other bodies, in which physical and practical tests of cotton, new and old, are carried out, there is

great interest at the Institute and in the industry in the question of instrumentation, and particularly the possibility of forecasting the spinning properties of cotton from physical measurements. Members could see a range of such instruments, including some of foreign manufacture and some made at the Institute. The problem is not an easy one, and indeed may not be completely soluble; but advance has been made, and broad differences in the spinning properties of cotton can now be detected rapidly with the aid of purely physical tests.

OBITUARIES

Prof. H. H. Dixon, F.R.S.

THE death of Prof. Henry H. Dixon on December 20 severs a link with a past generation of botanists and with a classic advance in botany. He was born on May 19, 1869. He was one of a family of seven brothers and two sisters; two of his brothers, and previously his father's brother, were university professors. He had a distinguished career as a student in Trinity College, Dublin, being a classical scholar of some note; he then added to his laurels by obtaining a natural science 'moderators'hip', taking first-class honours, and continued his studies under Strasburger in Bonn, under whom he commenced research in the two major fields to which he contributed so much in later life.

Bonn was a centre of cytological work and, though it is often forgotten now, Dixon was a contributor of some note in the Strasburger school to the work then being done on meiosis. A later paper communicated to the Royal Irish Academy in 1895 was probably the first expression of the view that the appearance of bivalents is due to the approach together of chromosomes, rather than to the splitting of some pre-existent structure, thus giving the first indication of a 'reduction division'. His observation of 'waves of nuclear division' passing across endosperm suggested a mitotic hormone, an observation which has yet to be investigated more fully.

Dixon's interest in cytology and his contributions to it were, however, completely overshadowed by the importance of his work on movements of water and on the status of water, or water relations, in the plant.

His life-long friendship with Prof. J. Joly had, as one of its fruits, the close collaboration between himself, a botanist, and a physicist, and from this emerged the classic theory, spoken of as the 'cohesion theory', to explain the rise of water (sap) in trees and other plants. This hypothesis was developed in the 1890's and extended by notable contributions on the cohesion of water and of sap and by a series of papers on the osmotic relations of plant tissues.

Dixon's originality of mind showed itself in many suggestions which were not followed up in the rather small School of Botany of Trinity College, Dublin. As early as 1892 he had shown how to grow seedlings in sterile culture, and foreshadowed, had the method been developed more fully, the tissue- and root-culture techniques so much used at the present time. He suggested the differential manometer for estimation of respiration-rates in 1902, though he did not develop it as a research instrument. Prof. Dixon also suggested (in a letter in *Nature*) the mutagenic effects to be expected of cosmic radiation, before Müller and the genetical world had come to accept or even consider this view.

In later years his work on transport of solutes and on permeability caused him to suggest hypotheses which, while not accepted later by himself or others, proved to be an effective stimulus both to his own student, Mason, and many other workers elsewhere.

Recognition of Prof. Dixon's qualities came relatively early; he succeeded to the chair of botany in Trinity College in 1904 and was elected to fellowship of the Royal Society in 1908. He was awarded the Boyle Medal of the Royal Dublin Society in 1917 and gave the Croonian Lecture before the Royal Society in 1937. He had been president of the International Botanical Congress and of the Royal Dublin Society, and also of Section K (Botany) of the British Association. He was an honorary fellow of Trinity College, Dublin, an honorary member of the American Society of Plant Physiologists, a Commissioner of Irish Lights and played an active part in many other national and international organizations.

The importance of the School of Botany in Trinity College, Dublin, under his guidance causes one to forget that the staff of this School during sixty years has been only two—the professor and his assistant. No memoir, however short, would be adequate if it referred merely to Prof. Dixon's academic distinction without mention of his very genial personality and of the atmosphere of the School of Botany in Trinity College, Dublin, which he created and which, unfortunately, owing to its small size, so comparatively few of the younger generation of botanists have been able to enjoy.

T. A. BENNETT-CLARK

HENRY DIXON began his university course in natural science under two good men, E. P. Wright, Sir Almroth's uncle, and H. W. Mackintosh, a wonderful lecturer, who looked down his microscope and saw the marvellous works of his Creator. He knew and taught that life begins with a single cell and develops in an orderly manner.

Wright, systematist and traveller, enriched both the Herbarium, which housed Harvey's type specimens of algae, and the lovely Botanic Gardens. Dixon, soon his successor, opened his own professorial sessions with an introduction to the microscope and went on to unicellular organisms. He illustrated the great ideas of evolution and heredity by precise studies in cytology and morphology. No one could escape a knowledge of bacterial and fungal infection, or of elementary ideas in general physiology.

It was my good fortune to begin under Wright and Mackintosh, and to be in Prof. Dixon's first class. I accordingly witnessed the development of his fine course, published as 'Practical Plant Biology' (1922 and 1943). Years afterwards a distinguished surgeon told me that it was the first thing that had really made him think. For the practical classes, which might run to 150, about a dozen demonstrators were taken on.

The successes of later years stemmed from Dixon's careful planning of the School of Botany, opened in 1907, which replaced the few residential rooms in the Front Square. The new Herbarium was added in 1912. The moving of collections and elimination of insects was heavy work. Into the eight-acre Botanic Gardens, moved to Balls Bridge in 1806, Dixon had up to some twenty years ago introduced more than seven thousand species, including Arthur Kerr's notable collection of Siamese orchids which Sidney Wild, the head gardener, tended so sedulously.

No mention of the T.C.D. School would be complete without reference to the red-headed lad, Joe Murray, who appeared in 1905-6 and remained there until his death on January 24 of this year. With the professor, "Joe", Wild and Polly, head of the College groundsmen, I spent many happy years.

The delightful atmosphere of our chief's laboratory could be traced back to the home with his mother and sisters—enlivened by frequent visits from his brothers and their families. It was the same in his own home with his wife, who cared for him with such devotion. I recall his happiness when telling me that their three sons (all of whom have had distinguished careers) had never caused him one moment's anxiety.

W. R. G. ATKINS

Mr. R. S. Whipple

It was with a deep sense of loss that his large circle of friends heard of the death of Robert Stewart Whipple, which occurred at his home in Highgate Village on Sunday, December 13. His father, G. M. Whipple, was superintendent of the Kew Observatory, and was himself very interested in scientific instruments. Thus Whipple grew up with scientific instruments and acquired a love for them which coloured his whole life.

Whipple was educated at King's College School, Strand, and on leaving went in 1888 directly into the Kew Observatory, staying on for three years after his father's death in 1893 with his successor, Dr. Charles Chree. In 1896 for two years he was assistant manager to L. P. Casella, and then he joined the Cambridge Instrument Company, which Horace Darwin in partnership with A. G. Dew-Smith had founded in 1881. In 1909 Whipple and C. C. Mason became joint managing directors. Under their management the firm developed and acquired a high reputation for the quality of its products. Of these, mention may be made of the 'rocking-microtome', a piece of beautiful design by Sir Horace Darwin, and a range of temperature-measuring instruments. Whipple was responsible for the introduction of the Ferry radiation recorder, of which the firm bought the rights for Great Britain. He himself designed an instrument for reading temperatures direct on the gas scale; this is used largely to-day in industry as a sub-standard.

He retired from active management in 1935, but remained a director, and in 1939 was elected chairman of the Board; from this he retired in 1949 for reasons of health, but continued to take a keen interest in the firm. During all this time he took a great personal interest in the employees of the company, which they fully reciprocated, feeling that in him they had a sincere friend.

Whipple was a valued member of the societies connected with physics and a constant attendant at their meetings. He was a member of the Council of the Physical Society during 1909-14 and again during 1925-36, a vice-president from 1914 until 1916 and treasurer from 1925 until 1935. He was president of the Optical Society in 1920-22. He was a founder member of the Institute of Physics in 1920, and served on its Board for a total of twenty-one years between 1920 and 1945, and on its Finance Committee from 1945 onwards. His services in the cause of physics received their highest recognition in his election to the presidency of Section A (Mathematics and Physics) for the Dundee meeting of the British Association in 1939, which, however, was

abandoned due to the outbreak of war—one of the few cases in which that honour has fallen to an industrialist.

Whipple was always interested in the history of science and was a collector of early scientific instruments; of these he built up a wonderful collection which he most generously presented to the University of Cambridge in 1944; but it was not until 1951 that a small building was provided for their display, and the Whipple Museum was opened by the Vice-Chancellor on May 5. Now that "History and Philosophy of Science" has (partly perhaps due to the inspiration of this Museum) been included as a half-subject in the Natural Sciences Tripos, candidates will find the study of the actual instruments, that this Museum affords, of very real help. When the plans for the new Science Laboratories at Cambridge are further advanced, it is to be hoped that a larger building will be found, in which, with the Whipple instruments as a nucleus, the great number of instruments that Dr. R. T. Gunther proved to exist in Cambridge by the collection he was able to get together in June 1936 will again be assembled to grow to a collection worthy of the University.

In addition to the instruments, Whipple gave his library of scientific books, which included many of the rare early ones. He hoped that these might eventually be housed near the instruments, so that an instrument and its description can be studied together.

He also handed to trustees a fund of £3,300—later increased to £8,300—to be used for the purchase of instruments and books.

Whipple was a man of wide interests and engaged in many activities, serving on many committees; these will miss his wise guidance and support—often of a substantial kind. He will long remain in the hearts of those who served with him.

In 1939 he was elected president of the Highgate Literary and Scientific Institution, into which he put new life by his energy and help, and it is now a strong society. Only a little more than a week before his death, he gave the sum of £5,000 to trustees to be used for the benefit of Highgate Village.

Whipple was a fine example of an English gentleman, upright and honourable, full of kindness and sympathy, ready to help in any good cause and a man of wise counsel and sound common sense. He had great charm of manner which endeared him to all with whom he came into contact. He married Helen Muir, daughter of a Glasgow engineer and sister of James Muir, professor of natural philosophy in Glasgow; they celebrated their golden wedding in June 1953. Their son, George, is chairman and managing director of Messrs. Hilger and Watts, makers of optical scientific instruments, and a daughter, Ruth, is the wife of Prof. J. F. Young, professor of pathology in the University of Aberdeen.

R. S. CLAY

We regret to announce the following deaths:

Mr. P. S. Riddale, director of the Charles Lathrop Paik Forestry Foundation, formerly editor of the *American Forestry Magazine* (1912-22) and of *Nature Magazine* (1923-37), on December 23, aged eighty-one.

Mr. H. W. J. Stone, honorary secretary and treasurer during 1933-45 of the Parliamentary Science Committee and editor of its publication *Science in Parliament*, on January 17, aged seventy-six.

NEWS and VIEWS

Royal Military College of Science:

Prof. C. J. Tranter, O.B.E.

PROF. C. J. Tranter has been appointed Bashforth professor of mathematical physics in the Royal Military College of Science, Shrivenham, in succession to Prof. O. G. Sutton, who vacated the chair recently on his appointment as director of the Meteorological Office. Prof. Tranter joined the Ballistics Directorate of the Research Department, Woolwich, in 1931 as a junior assistant, after taking his degree at Oxford, where he had been a mathematical scholar of Queen's College, and his career has been in government service throughout. He joined the Military College of Science, as it then was, in 1935 as senior lecturer in gunnery and mathematics, was promoted to assistant professor in 1941 and during the long illness of the late Prof. Wright was virtually in charge of the Gunnery and Mathematics Branch. Since 1945 he has been head of the Mathematics Branch, and in 1947, after the post-war reorganization of the College, was appointed associate professor of mathematics. During and since the Second World War, Dr. Tranter has been a member of several of the research committees of the Ministry of Supply, and he has published a considerable amount of work, mainly on the application of integral transforms to the boundary-value problems of mathematical physics. Prof. Tranter is a D.Sc. of Oxford and was made an O.B.E. in the Coronation honours list.

Agriculture in the University of Aberdeen:

Prof. A. B. Stewart

DR. ALEXANDER BOYD STEWART has been appointed to the Strathcona-Fordyce chair of agriculture in the University of Aberdeen, in succession to Prof. T. L. Bywater, who has gone to the University of Leeds. Dr. Stewart was educated at Logie Coldstone School, Robert Gordon's College and the University of Aberdeen, where he graduated M.A. in 1925, B.Sc. in chemistry with first-class honours in 1928, and Ph.D. in 1932. After graduating in pure science, Dr. Stewart studied under the late Prof. Hendrick, the first incumbent of the chair to which he now succeeds, and then proceeded to Zurich to work under the late Prof. Wiegner. Returning to Scotland in 1931, he was a research student at the Macaulay Institute for Soil Research and was appointed to the staff in 1932. As head of the Department of Soil Fertility at the Institute, Dr. Stewart developed and extended the work of field experimentation with special reference to the maintenance and improvement of soil fertility. In 1945 he was appointed deputy director of the Macaulay Institute and has since served on numerous technical committees. In 1945, he spent six months in India advising the Central Government on problems of soil fertility and crop production. In collaboration with Dr. F. N. Woodward and the late Mr. J. P. Maxton, he undertook during 1949-51 a survey of agricultural, forestry and fishery products, and their utilization in the United Kingdom. Dr. Stewart has given his services in an advisory capacity to the Forestry Commission and, during 1952, visited the United States of America as a guest speaker. The Macaulay Institute for Soil Research, in parting with him, rejoices in his appointment as a successor of the late Prof. James Hendrick, to whose energy and enthusiasm the foundation of the Institute in Aberdeen was due in large measure.

School of Physics in the University of Sydney

THE previous head of the School of Physics of the University of Sydney was Prof. O. U. Von Willer, who retired in 1946 having held the post for twenty-three years, and the chair was vacant for six years until September last year when Dr. Harry Messel was appointed as the new head. Prof. Messel graduated in Canada from the Royal Military College and Queen's University, Kingston, Ontario, with honours degrees in physics and mathematics, and then went for a year to Scotland (University of St. Andrews), carrying out postgraduate studies in mathematical physics. During the following three years, spent at the Institute for Advanced Studies, Dublin, he took a keen interest in cosmic ray theory, in particular the theory of cascade processes, and it was there that he succeeded in giving an analytical solution for the long-standing fluctuation problem in cascade theory. This work was followed by a series of papers in which he developed the mathematical theory of one- and three-dimensional cascade processes. After a year at Adelaide, South Australia, Prof. Messel was appointed to the chair at Sydney and took energetic steps to establish a large and flourishing research school, concentrating on experimental and theoretical studies of the cosmic radiation and on modern theoretical physics, especially nuclear theory.

Prof. Messel has been joined by Dr. E. P. George from London, who will look after the experimental programme; and further new appointments in the experimental team are Dr. A. J. Herz (London), Dr. D. D. Millar (Manchester) and Dr. H. D. Rathgeber (Melbourne), and, in the theoretical team, Dr. J. Blatt (Illinois, U.S.A.), Dr. S. T. Ma (National Research Council, Canada) and Dr. M. R. Schafroth (Liverpool). A number of further appointments will be made shortly, bringing the number of permanent academic staff in the School to twenty-one. Two students from universities in England are already in Sydney, completing their doctoral training, and a number of postdoctoral Fellows from overseas will be arriving early in the new year. To supplement the limited funds available for research from University sources, Prof. Messel has secured support from Australian business men, with the excellent result that £25,000 is available for research equipment this year, and a similar sum promised annually for the future. This has been secured by setting up a Nuclear Research Foundation within the University of Sydney, which allows private individuals and industries to become members. Experiments are planned on air-showers, underground cosmic rays and spectrum measurements. Theoretical investigations are planned on cascade phenomena, fundamental particles, solid state, etc.

South Wales Laboratories of the British Iron and Steel Research Association: Mr. S. S. Carlisle

WE regret that in *Nature* of January 30, p. 191, it was stated that Mr. D. Luther Phillips was being succeeded as head of the South Wales Laboratories of the British Iron and Steel Research Association by Dr. J. Pearson. This is incorrect; Dr. Pearson is head of the Chemistry Department of the Association and is temporarily taking over the duties of head of the Steel-making Division. Mr. Luther Phillips is being succeeded by Mr. S. S. Carlisle. Mr. Carlisle graduated at The Queen's University, Belfast (College of Technology), in electrical engineering and later continued his studies

at the College, being granted the degree of M.Sc. in 1942. During the course of higher study he was appointed a temporary lecturer in radio and radio-physics at the College. In 1942 he joined the staff of the Director of Scientific Research, Admiralty, and was stationed for four years on H.M.S. *Excellent*, Portsmouth, where he was engaged on the development and trials of radar and gun control equipment, being particularly concerned with the development of electrical predictors. In 1946 he joined the staff of the British Iron and Steel Research Association, and in 1947 was appointed head of the Instrument Section of the Physics Department. Mr. Carlisle has been closely associated with the industry's co-operative work on instrumentation, particularly that of open-hearth furnaces, which has placed Great Britain in the forefront of steelworks instrumentation practice. He is a member of the Council of the Society of Instrument Technology.

Training and Supply of Graduate Teachers In Mathematics and Science

In reply to a request in the House of Commons on January 21 for a statement on the report of the National Advisory Council on the Training and Supply of Teachers with particular reference to graduate teachers of mathematics and science, the Minister of Education, Miss F. Horsbrugh, stated that she accepts the broad conclusions of the report, and that she is consulting the other interests principally concerned to see how the needs of the schools for a better supply of these teachers can best be met. She will also be asking the local education authorities to ensure that the most effective use is made of the graduate teachers of science and mathematics available to them now and in the future.

Threat of Atomic Warfare

READERS of the *Bulletin of the Atomic Scientists* will have noticed that the hands of the clock which forms the distinctive coverpiece of the *Bulletin* have been moved forward so that now they stand at two minutes to midnight. This is to direct attention to the recent announcement that an atomic test involving both fission and thermonuclear reactions was conducted by the U.S.S.R. on August 12 and to warn members of all nations of the great danger of an untoward event acting as a trigger for the eruption of atomic or thermonuclear warfare. In an article in the October number of the *Bulletin* (9, 294; 1953) entitled "The Narrowing Way", the editor, Dr. E. Rabinowitch, expresses the apprehensions which many Americans feel. He considers that unless special care is taken it may only be a few more swings of the pendulum before atomic explosions strike midnight for Western civilization. In 1945 or 1946, he states, the elimination of atomic weapons from national arsenals through an international control mechanism, substituting mutual interdependence for mutual fear, had a slight chance of success, but it now has none and will not until the present cleavage of the world into two sharply opposed power camps disappears. Dr. Rabinowitch maintains that the Western countries are faced with the inevitable prospect of a "cold peace", precariously supported by a mutual threat of atomic and thermonuclear annihilation, and that in order to strengthen this peace it is necessary for the United States of America to create a powerful and universal fear of, and revulsion to, war by presenting to the world a sober account of the present, and reasonable estimate of

the anticipated, destructive capacities of the atomic and thermonuclear weapons in American and other hands. In addition, aggression must be made clearly unprofitable, and, he states, American policy must be directed towards maintaining unity and collective security in the non-communist world.

Linen Industry Research Association: Report for 1953

THE report of the Council of the Linen Industry Research Association for the year ended September 30, 1953 (pp. 20; from the Association, Belfast, 1953), records the completion of the post-war development programme of the Institute laid down in 1945. Membership of the Association now totals 285; but although the grant-earning income increased, the total income decreased slightly through a reduction in the grant from the Flax Development Committee and in the revenue from patents. Promising results have been obtained with a prototype stapling machine for flax fibre, of which the object is to improve levelness during preparing and dry spinning. Investigations continued on productivity in flax spinning, on the drafting of flax and rayon staple fibres on flax machinery with the object of improving the regularity of the yarns, on the elimination of shading effects in plain dyed rayon staple fabrics and on yarn friction. Advances have been made in the use of electronic irregularity testers for routine mill tests for the control of yarn quality, and of the 'Lirna photostubber' to locate the causes of faults in production. In fundamental work on the relation between yarn strength and cloth strength, tests have been completed for cloths ranging in weight from 7 to 12 oz./sq. yd. New instruments have been developed for studying the physical properties of size materials and correlating these properties with performance in the loom. Further advances have been made in producing the crease-resistant finish on linen fabrics, and bulk trials on finishing linen fabrics to improve the wearing qualities are in progress, while a wash-fast flameproof finish applied to linen fabrics has given satisfactory results under user conditions. In moving the adoption of the report and accounts at the annual general meeting on December 11, 1953, the chairman of the council, Mr. H. B. McCance, said that perhaps the greatest contribution the Association has made to the industry has been its unconscious education in the scientific approach, and he referred particularly to the flow of staff from the Research Association to member firms. The director, Dr. A. J. Turner, stressed the plea in the report for greater co-operation from member firms in putting their problems to the Association's staff. He also reported that the experimental work on bleaching linen yarn in package form has now reached the stage of industrial application.

Australian and New Zealand Association for the Advancement of Science

THE report of the twenty-ninth meeting of the Australian and New Zealand Association for the Advancement of Science, held in Sydney during August 1952, edited by J. F. Kefford, has been published (Vol. 29; pp. 386. Sydney: Government Printer, 1953). It includes the presidential address of Sir Douglas Copland on "Authority and Control in a Free Society", and those of the presidents of the several sections, with lists of papers read to the sections and the report of the standing committee of Sections C (Geology) and P (Geography and Oceano-

graphy) on research on eustatic sea-levels in Australia and New Zealand during 1949-52. The sectional addresses include those of Prof. M. L. Oliphant on the research school of physical science in the Australian National University; Prof. A. K. Macbeth on some aspects of the chemistry of monocyclic terpenes; Prof. F. W. Whitehouse on the Mesozoic environments of Queensland; I. M. Mackerras on zoology and medicine; Hon. P. M. Hasluck on the future of the Australian aborigine; Prof. W. Prest on the future of private enterprise; Prof. H. H. Davis on the control of dynamic loading on machine components and structure; E. V. Keogh on virulence and infectivity; Dr. H. C. Forster's review of programmes for agricultural research in Australia; Dr. F. H. S. Roberts on host specificity of livestock parasites in Australia; Prof. V. J. Chapman on problems in ecological terminology; Prof. N. L. Edson on the metabolism of the sugar alcohols; and C. Rudduck on geography and national development. Also published is Dr. J. R. Price's Liveridge lecture on some recent developments in the study of the chemistry of Australian plant products.

Legumes In Agriculture

LEGUMES have been grown as crops for at least six thousand years, though the scientific explanation of their value was not discovered until late in the nineteenth century. How best to incorporate these important plants in the various agricultural systems of the present day is clearly a fundamental question, and, as a step towards providing an answer, the United Nations Food and Agriculture Organization has carried out a review of leguminous plants throughout the world. The report, published under the title "Legumes in Agriculture" (F.A.O. Agricultural Studies No. 21. Pp. 367. Rome: F.A.O.; London: H.M.S.O., 1953; 15s. or 3 dollars), is by R. O. Whyte, G. Nilsson-Leissner and H. O. Trumble. In temperate zones, with ample and well-distributed water supply, wild white clover has become the key factor in ley farming, with subterranean clover as an efficient counterpart in the pastures of South Australia. Little, however, is known regarding the use of legumes in tropical and sub-tropical regions, and literature on the subject is very meagre. In consequence, one of the most valuable parts of the publication is the section giving the results of a questionnaire sent out by the Organization during 1951 as to the occurrence and use of leguminous plants in these parts of the world. The information is conveniently reviewed on a geographical basis, and it may well be that further work on the adaptation and utilization of legumes in the tropics would best be organized on a regional basis. The chief limiting factors appear to be social and economic rather than lack of species, though there is great scope for selection and breeding within existing material. Further, it seems likely that the position of the leguminous crop in the agricultural system will differ from that in temperate lands, the trend being away from a mixed legume/grass association towards a separate but contiguous cultivation. The review should also be valuable as a book of reference, for it includes an alphabetical list of genera with notes on each, tables summarizing the characteristics of herbaceous and shrubby legumes and a bibliography.

A Coniferous Petrified Forest In Patagonia

Two species of fir cones, both of which have been named and incompletely described in earlier publica-

tions, are described with anatomical details by Mary Gordon Calder in "A Coniferous Petrified Forest in Patagonia" (Bull. Brit. Mus. (Nat. Hist.): Geol., 2, No. 2, 97-138; 1953; 12s.). This account is welcome as a full description of a locality where the petrified tree trunks are said to be 100 m. long and 10 m. round; its petrified fir cones have sometimes been sliced, polished and shown in museums as things of beauty. The forest is probably of younger Mesozoic age and was overwhelmed by volcanic ash. Of the two species of cones, one, *Araucaria mirabilis*, is like the Australian *Araucaria bidwillii* but different from the South American species of to-day. Radish-like bodies associated with the cones are recognized as the seedling hypocotyls of an *Araucaria* of this group; they had previously been a mystery. The other cone, with the unfortunate name of *Pararaucaria*, has nothing to do with *Araucaria* but is apparently an extinct member of the Taxodiaceae, its characters being found scattered among the genera of to-day. It is interesting that this family is now absent from South America. It is good to see that two of the many fossil genera assigned to a position between *Araucaria* and *Pinus* have been removed.

Natural History of Bombed Sites

A RECENTLY published illustrated brochure summarizes in a convenient and popular manner the record of colonization of the bombed sites of London by plants and animals ("The Natural History of the City." By R. S. R. Fitter and J. E. Lousley. Pp. 36+13 plates+1 map. London: The Corporation of London, Guildhall, E.C.2; 1953. 2s. net). The introductory chapter is largely a very condensed historical summary of the natural history of the City. It is followed by accounts of the plants, arranged according to their mode of dispersal, and the animals the presence of which is not so obviously connected with the results of bombing. In an appendix all the recorded species are listed. Though the booklet is not intended as a scientific contribution, it gives a good deal of interesting data on ecology and rate of dispersal. Clearly the opportunities to study this unexpected and ill-gotten phase in the City's development will, it is hoped, not long remain; but it is still possible among the ruins to observe rarities in both the plant and animal kingdoms.

British Mammals

SINCE the discontinuation of *The Zoologist* in 1916, the study of mammals in Great Britain has been greatly handicapped by the lack of a specialist journal. It is hoped to remedy this deficiency by publishing in *Oryx* a regular section devoted to the natural history and conservation of British mammals. The twin aims of the section are well illustrated by two articles in the current issue of *Oryx*, one on the field study and identification of British bats, by Michael Blackmore, the other on the case for a close season for deer, by G. K. Whitehead (2, No. 3; November 1953). In addition, it is hoped to publish regularly short notes on matters of general rather than local interest, to review books on or largely devoted to British mammals, and to abstract from local natural history journals any papers or notes of more than local interest. Editors of local journals and secretaries of the mammal sections of local natural history societies and field clubs are invited to send to Mr. R. S. R. Fitter copies of their journals or reprints of any sections of articles relating to

mammals. The address is Drifts, Chinnor Hill, Oxford.

Speech for Deaf Children

RESEARCH in the Department of Education of the Deaf at the University of Manchester has shown that deaf children less than three years old can begin to learn to understand speech through lip-reading as a result of home training by their parents (*Mem. and Proc. Manchester Lit. and Phil. Soc.*, 1952-53). This has been reported by Prof. A. W. G. Ewing, director of the Department, who has discovered that a majority of pupils in schools for the deaf have been found to be deaf from before the age of two. Principles and methods have been evolved which constitute a genetic and simplified approach to speech for the deaf. Investigations which have been taking place over the past twenty-four years have shown that few children are totally deaf and suggest that special nursery schools should be an essential part of educational provision to prevent dumbness. A combination of lip-reading with the scientific use of modern group and individual hearing aids greatly facilitates the development of speech, language and social adequacy by pupils in schools for the deaf.

Boris Kidrich Institute of Nuclear Sciences, near Belgrade

THE rapid growth in recent years of a network of scientific institutions throughout Yugoslavia and, in particular, the establishment and development during the past five years of the three major institutions, the Rudjer Bošković Institute at Zagreb, the Josif Stefan Physical Institute at Ljubljana and the Institute for the Research on the Structure of Matter at Vinča, near Belgrade, was largely due to the efforts of Boris Kidrich. He was a chemist by training, but he devoted himself, as statesman and economist, to the task of the social, economic and scientific development of his country. Boris Kidrich died on April 7, 1953, and in recognition of his work for science the general assembly of the Institute of Research on the Structure of Matter unanimously agreed on April 13 to rename the Institute as the Boris Kidrich Institute of Nuclear Sciences. Accordingly, Vol. 3 (August 1953) of the Institute's scientific publication, formerly *Recueil de Travaux de l'Institut de Recherches sur la Structure de la Matière*, bears the new title *Bulletin of the Institute of Nuclear Sciences "Boris Kidrich"*. In addition to a photograph of Boris Kidrich as frontispiece, it contains nineteen original scientific articles dealing mainly with instruments developed at the Institute for investigations in nuclear physics.

Geography: Journal of the Geographical Association

THIS year the Geographical Association celebrated the sixtieth anniversary of its founding (see *Nature*, January 16, p. 99), and the occasion also marks the diamond jubilee of the Association's quarterly journal, now called *Geography*. A special, enlarged jubilee issue has been published which contains several papers on the work and history of the Association by T. O. Warrington, H. J. Fleure, O. J. R. Howarth and others. Founded by B. B. Dickinson, H. J. Mackinder, A. J. Herbertson, H. R. Mill and others for furthering the study of geography on a scientific basis in schools and universities, the Association has grown to be an organization of several thousand members with branches in many countries. Its journal once chiefly contained papers on teaching

and method, but now it has developed into a leading publication in geographical research. The Association has in turn moved its library from Oxford, Aberystwyth and Manchester, and is now, by courtesy of the City Corporation, housed in Sheffield in a branch of the City Library.

Ergonomics Research Society: Annual Conference

THE fourth annual conference of the Ergonomics Research Society will be held at Ashorne Hill, near Leamington Spa, Warwickshire, during April 5-8, under the chairmanship of Sir Frederic Bartlett, formerly professor of experimental psychology in the University of Cambridge. The conference will be opened by Sir George Barnett, H.M. chief inspector of factories, and the speaker at the closing session will be Dr. Leonard Carmichael, secretary of the Smithsonian Institution, Washington, D.C. The annual general meeting of the Society will be held on April 6. The conference will be open to non-members of the Society on payment of a fee of 30s. All those wishing to attend the conference, whether members or otherwise, must complete an application form by March 29 and return it to K. F. H. Murrell, "Spinneys", Marlpit Lane, Redditch, Worcs, from whom further information can be obtained.

Acoustics of Orthoptera: Symposium near Paris

A SYMPOSIUM on the acoustics of Orthoptera, the first of its kind ever to be organized, will be held near Paris in the Laboratoire de Physiologie Acoustique, Institut National de la Recherche Agronomique, Jouy-en-Josas, Seine et Oise, during April 5-8. The fields to be covered will be as follows: acoustic emission in Orthoptera (standardization of definitions and of physical acoustics applied to the emissions, techniques of recording, techniques of physical analysis, mechanisms of emission, emission behaviour, and techniques of artificial reproduction of the sounds); acoustic reception in Orthoptera (physiological analysis of reception (action potentials) and reception behaviour); behaviour of Orthoptera under artificial acoustic stimuli; and bibliography. Besides the usual short papers and contributions, the following specialists will give general reviews on certain topics and reports on the work which is being done in their respective countries: Germany, Prof. H. Autrum (University of Würzburg) and Prof. W. Jacobs (University of Munich); Great Britain, Prof. R. J. Pumphrey (University of Liverpool); Italy, Prof. E. Benedetti (University of Parma); and United States, Prof. H. Frings (Pennsylvania State College). The languages for the symposium will be French, English, German and Russian. Further information can be obtained from the Laboratoire de Physiologie Acoustique at the above address.

Announcements

PROF. H. H. READ, professor of geology in the Imperial College of Science and Technology, London, and Prof. Louis Royer, professor of mineralogy and crystallography and dean of the Faculty of Sciences of the Institut d'Hygiène et de Médecine d'Outre-Mer de l'Afrique du Nord, have been elected *correspondants* for the Mineralogical Section of the Paris Académie of Sciences in succession to the late Prof. A. Bigot and Prof. P. Niggli.

THE thirty-eighth Guthrie Lecture of the Physical Society will be given by Sir Geoffrey Taylor in the Science Museum, Exhibition Road, London, S.W.7,

on March 26 at 5 p.m., his subject being "Diffusion and Mass Transport in Tubes". The Lecture is open to the public.

FOLLOWING the annual general meeting of the Textile Institute, Manchester, to be held at The Queen's University, Belfast, on April 30, Dr. D. A. Clibbens, until recently head of the Chemistry Division of the British Cotton Industry Research Association, will deliver the Mather Lecture for 1954, his subject being "Cellulose Chemistry and the Textile Industry". The Mather Lecture, first delivered in 1919, is held in memory of Sir William Mather, president of the Institute during 1915-17.

THE Histochemical Society will meet at Atlantic City, New Jersey, during April 16-17, following the session of the American Society for Experimental Pathology. A feature of the meeting will be a symposium on "Basophil Components of Cytoplasm", to be held on the afternoon of April 16. Further information can be obtained from the secretary of the Society, Dr. R. D. Lillie, Department of Health, Education and Welfare, National Institutes of Health, Bethesda 14, Md.

A CONFERENCE on "Unit Processes of Oxidation", arranged jointly by the Institution of Chemical Engineers, the Chemical Engineering Group of the Society of Chemical Industry, the Chemical Engineering Group of the Koninklijk Instituut van Ingenieurs (Royal Institution of Engineers) and the Section for Chemical Technology of the Koninklijke Nederlandse Chemische Vereniging (Royal Netherlands Chemical Society), will be held in The Hague during May 6-7, with a third day reserved for excursions. Particular stress will be laid on the chemical engineering aspects of unit processes of oxidation. The conference language will be English. Further information can be obtained from the secretary of the British organizing committee, R. O. Odams, Institution of Chemical Engineers, 56 Victoria Street, London, S.W.1.

THE Spectrochemistry and Colorimetry Group of the Austrian Chemical Association is holding its fifth international colloquium in Grunnden (Salzkammergut) during August 30-September 3. As in former years, the colloquium will be divided into two parts, absorption and emission spectroscopy; for the former, the theme will be the application of molecular spectroscopy to the examination of technical artificial fibres, and for the latter, the discussion will deal chiefly with non-conductors and the alloys of copper. Interested organizations from other countries are invited to attend and should write before the end of March to Arbeitsgruppe für Spektrochemie und Kolorimetrie im VOCh, Wien IX, Sennengasse 2 (Institut für gerichtliche Medizin). Each national organization will be allowed to submit five papers, and short summaries of these should be sent in by May 30.

THE Atomic Energy Research Establishment, Harwell, is holding a second radioisotope conference in Oxford during July 19-23. The conference will be concerned with medical applications (including therapy and diagnosis), biological applications (including agriculture and biochemistry), chemistry and metallurgy, and physics, engineering and industrial applications. The last date for applying for membership at the normal fee is February 28, after which a late fee will be payable. Application forms and

further information can be obtained from the Conference Secretary, Second Radioisotope Conference, A.E.R.E., Harwell, Berks.

THE second (October 1952; 18 papers), third (December 1952; 23 papers) and fourth (March 1953; 28 papers) lists of scientific reports produced by members of the Atomic Energy Research Establishment, Harwell, and now available for sale at H.M. Stationery Office are published in the *Atomic Scientists' Journal* (3, No. 1, 58; 1953). They include bibliographies on americium, fission, the electrostatic separation of minerals, and the drying of gases and determination of moisture in gases, and reports of symposia on thin films and the handling of radioactive and toxic substances. The reports bear dates between July 1949 and November 1952.

APPLICATIONS are invited for Lady Tata Memorial Fund grants, scholarships or fellowships to scientific workers of any nationality for research on diseases of the blood, with special reference to leukaemia or any aspect of malignant disease connected with leukaemia, during the academic year beginning on October 1 next. Grants are made for research expenses; scholarships are awarded as personal remuneration, their normal value being £800 a year for whole-time research; and fellowships are for workers with considerable research experience, the stipend being £1,000 a year. Applications must be submitted before March 31, and the awards will be announced in June. Application forms and further information can be obtained from the Secretary of the (European) Scientific Advisory Committee, Lady Tata Memorial Trust, c/o Medical Research Council, 38 Old Queen Street, London, S.W.1.

THE Medical Research Council is offering a number of fellowships for the academic year 1954-55, as follows: *Rockefeller travelling fellowships in medicine* (2,700 dollars a year, or 3,600 dollars for married men) for graduates resident in Great Britain with previous research experience in clinical medicine or surgery, or in some other branch of medical science, to work at a centre in the United States or elsewhere abroad before taking up positions for higher teaching or research in Britain; *Elis Lilly travelling fellowships in medicine*, of a similar nature to the Rockefeller awards; and *Dorothy Temple Cross research fellowships in tuberculosis* (£850 a year, or £900 for married men) for British subjects to devote themselves to the advancement of knowledge of tuberculosis at a centre outside Great Britain. All these fellowships carry, in addition, an allowance for travelling and other expenses. Application forms (to be returned by March 15) and further particulars can be obtained from the Secretary, Medical Research Council, 38 Old Queen Street, Westminster, S.W.1.

"METHODS OF THEORETICAL PHYSICS", by Prof. P. M. Morse and Prof. H. Feshbach, was advertised in *Nature* of January 16, p. v. The McGraw-Hill Publishing Co., Ltd., McGraw-Hill House, London, E.C.4, has asked us to state that the price of these volumes is £8 each; Part 2 consists of pp. 998-1978 of the complete work.

ERRATUM.—In the communication "Distribution of Radio-Frequency Brightness across the Solar Disk and the Derivation of a Model Corona", by P. A. O'Brien and O. J. Bell, in *Nature*, January 30, p. 219, the units of the distance from the centre of the disk in the graph for $\lambda = 1.4$ m. should be 0, 0.5, 1, 1.5 and not 0, 1, 2, 3 as printed.

EUROPEAN ASSOCIATION OF EXPLORATION GEOPHYSICISTS

MEETING IN MILAN

THE fifth meeting of the European Association of Exploration Geophysicists was held in Milan during December 2-5, when about a hundred and ten members were present, the president, D. T. Germain-Jones, being in the chair. After discussing affairs of business, the chairman announced the recent deaths of two founder members, M. Schlumberger and K. Röpke, and called the meeting to pay tribute to their memory: Marcel Schlumberger was internationally famous for his development of electrical measurements in boreholes which are, to-day, routine in the oil industry throughout the world; Karl Röpke was one of the early workers, under Prof. Mintrop, with the seismic refraction method of prospecting.

Of the twenty-two papers presented, eleven were on seismic, six on gravity, three on electrical, one on magnetism and one on general problems in exploration geophysics. R. Cassinis and E. Carabelli (Italy) opened with an account of a reflexion and refraction survey for thickness determination over the Del Forni glacier in the Italian Alps. Such investigations have a direct bearing on the exploitation of hydro-electric power, largely for the distribution of water for farming purposes, and large-scale surveys have already been carried out over the Swiss and French glaciers. A most disconcerting feature is that the number of glacial reservoirs has notably decreased in the past few years. By way of extreme topographic contrast, T. F. Gaskell (Great Britain) described the measuring technique and the results of the refraction surveys in the Atlantic, Pacific and Indian Oceans as part of the scientific programme of H.M.S. *Challenger* during 1950-52. An account of this seismic work has recently been published¹.

Three papers related to velocity measurement. The first, by F. Haastadik (Germany), implied that seismic computers are too apt to use continuous velocity/depth functions even when finite velocity changes are known to exist; but, in the discussion, several speakers refuted such a sweeping assertion. J. G. Hagedoorn (Holland) compared the vertical velocity measurements in a borehole with the bedding velocities obtained by refraction, but pointed out that dispersion might be greater for the much greater travel distances of the refracted impulses and, therefore, that these impulses would travel with a lower frequency and higher velocity. This would invalidate to some extent any conclusions as to anisotropy, while another adverse factor is that it is not possible to say explicitly what thickness of the refractor is traversed by the refracted (actually diffracted) wave in the bedding direction. The third paper, by J. Cholet and H. Richard (France), approached this matter of anisotropy in a more direct way. They measured travel times along various paths inclined up to 50° with the vertical and showed that a coefficient of anisotropy of 1.09 for clays and sands would compensate for the discrepancies of travel time observed.

On the theoretical side, M. Matichinski (France) proposed a simple but sufficiently exact method of dealing with elastic hysteresis in the propagation of seismic waves with particular reference to absorption, while T. Krey (Germany) presented three-dimensional formulae for the correction of the position of the

reflector for any refraction to which the reflected wave had been subjected.

The drilling of shot holes often poses difficult mechanical problems depending on the softness or hardness of the formations, the tendency for the walls of the hole to cave in and the loss of fluid circulation. G. Muratori (Italy) discussed the overall practical aspects and design details of the drilling machinery adopted in these various conditions; they included drills operated by high-pressure water jet, conventional rotary and percussion drilling and the very efficient diesel hammer especially suitable for the gravels and boulders of the Po valley.

It may seem surprising that, after a generation of seismic prospecting, the mechanism of the explosion and energy transmission at a shot point are imperfectly understood. The difficulty lies in the large number of controlling factors and the well-known requirement that a set of shot-point conditions is not entirely reproducible for check purposes. This situation was rendered more complicated by V. Colledan and A. M. Salem (Italy), who demonstrated that, with equal weights of an ammonium nitrate dynamite (sismite) and a nitro-glycerine dynamite (GDIMT), reflexion responses were greater for the former despite its 30 per cent lower strength and lower detonation velocity than the latter. Other explosives were also used in the test; but conclusive results cannot be given until many more experiments have been done; the results will be of some importance, as the ammonium nitrate explosives are much safer to handle in some climatic conditions than the nitro-glycerines. The safety factor in seismic work was further discussed by E. Merlini and A. M. Salem (Italy) in cases where the detonator circuits pass close to power lines, electric railways or deep well casings. The induced potentials set up in certain types of ground, especially during electrical storms, might result in premature ignition of the explosive unless precautionary disposition of the detonator leads is resorted to.

The final paper in the seismic session, given by L. Solaini and G. Uglietti (Italy), described an electronic blaster with a codified radio transmission of the shot instant designed to prevent 'noise' which may impair the received signal when using other blasters; all the usual operations from stand-by to shot-instant transmission are automatically provided for.

Contributions to gravity interpretation were made by three members. A. Marussi (Italy) discussed the meaning of the second differential parameter and adduced formulae relating it to the curvature and normal gravity derivatives. V. Baranov and J. Tasseaucourt (France) gave a mathematical exposition of certain approximations made in a paper on a practical method of calculating the vertical gradient which the first author had given at the Paris meeting of the Association. The vertical gradient and second derivative methods were applied by O. Roenbach (Germany), who showed how it is possible to locate a well on the down-throw side of a fault, given the depth of the up-throw side, other geophysical methods having failed.

A most interesting account of gravity measurements in the northern Adriatic Sea was given by O. Morelli (Italy). Here a tele-controlled Western

gravity meter, enclosed in a bathysphere weighing about half a ton, is lowered to the sea-bed, its position being fixed by radar intersection from fixed reflectors on land and at sea. The accuracy of measurement is estimated to be ± 0.05 mgal. The technique is, of course, several years old, but an important refinement in the new equipment is the inclusion of a compensator for microseisms, or seabed movements of relatively long period.

The meeting devoted some little time to the important subject of terrestrial tidal variation of gravity in precision studies, and, as the past president of the Association, A. van Weelden, had played a big part in initiating world-wide experiments to improve our knowledge in this respect, he was invited to take the chair for this section of the meeting. O. Morelli (Italy) reported on an extension of his diurnal investigations discussed at the Paris meeting and showed that curves calculated for northern Italy, lat. 45° N., long. 12° E., are applicable for all longitudes if times are suitably corrected. The curves yield an accuracy of 0.01 mgal. within 2 deg. of latitude. Extension to 13 deg. beyond this range also gives the same accuracy on multiplying the amplitudes by a suitable factor. M. Cuniatti and G. Inghilleri (Italy) provided a general analysis of the accuracy of the curves for any one station and proposed that the terrestrial tide be derived from an expression of the form:

$$\Delta g = F_1 \sin^2 \varphi + F_2 \sin 2\varphi + F_3,$$

where the constants, which are functions of the local hour angle and declination of the moon and sun, would be periodically determined and published. R. Tomaschek (Great Britain) discussed solutions which, by needing only little computing work by a survey party in the field, would avoid the necessity of making periodical calculations in a central institute. He advocated the use of permanent curves for the sun and the moon and a simplified current noon ephemeris of the moon.

J. Goguel (France) then reported the conclusions of the Tidal Committee, consisting of himself, O. Morelli and R. Tomaschek. They recommended publication in *Geophysical Prospecting*, the journal of the Association, of two kinds of tidal corrections for 1954, which should be tested by field parties as to their simplicity. The first kind consists of curves showing the continuous variation of the tidal forces for several selected latitudes, and the second consists of tables. Each is expressed by:

$$\Delta g = -A + N(\cos \varphi + \sin \varphi) \cos \varphi + S(\cos \varphi - \sin \varphi) \cos \varphi,$$

where φ is the latitude and N and S time functions of the moon and sun together. The tables are obtained by means of a tide predictor. By using a simple nomogram the tidal correction may be determined by means of N and S for any latitude.

O. Morelli and L. Sogaro (Italy) described the results of a magnetic survey designed to investigate the trend of the volcanic outcrops in the Lessini, Berioi and Euganei uplands as they disappear beneath the Venetian plain towards the Adriatic Sea. Two branches are apparent, one towards Venice and the other towards Chioggia.

In the electrical section J. J. Breusse and G. Huot (France) illustrated how, in the course of exploring for water, four hundred depth measurements mapped the top of a clay formation underlying the alluvium of the Catania plain (Sicily). The map showed the presence of an old river valley system which was

believed to be filled with permeable alluvium; five wells drilled over these channels were productive. The problem of electrical sounding in the case of dipping plane interfaces is usually approached through an approximate application of the electrical image method for horizontal interfaces. A few years ago, however, an exact but laborious solution of the general problem was formulated. This has recently been improved on by J. Chastenat de Gery and G. Kunetz (France), who illustrated their analysis with interpretation charts. A most informative paper was that given by J. L. Mathieu (France), who described the 'laterolog', a method for better recording of formation resistivity in boreholes. Here, a current of constant intensity is forced into the formation perpendicular to the wall of the hole as a sheet of predetermined thickness by means of a special electrode arrangement, the control system being automatic. The many advantages of the 'laterolog' over ordinary resistivity logs were explained and illustrated by numerous examples.

The one general paper, by O. Vecchia (Italy), discussed the application of electrical and seismic refraction measurements in the problem of building a subsidiary dam on the Lake of Molveno, near Venice. The depth to bedrock was given by refraction, while the permeable nature of the overlying detrital matter was determined by electrical measurements at a number of water-levels. The results showed that subterranean losses disappeared when the level of the lake was 160 ft. lower than normal.

The technical proceedings closed with three films: "Schlumberger Surveys", presented by courtesy of the Société de Prospection Électrique, Paris; and "Recording the Safe Way" and "Drilling the Safe Way", both by courtesy of the Society of Exploration Geophysicists, United States. A short report of the Committee on Safety, given by A. van Weelden, made it very clear that lively action has been and will be taken on this important facet of applied geophysics.

All the arrangements for the meeting were efficiently and generously made by A.G.I.P. Mineraria, which also organized a visit to their geological and geochemical laboratories and to a seismic party; here, a comparative demonstration of rotary and percussion drilling by winch and diesel hammer was most impressive. On the lighter side, sight-seeing tours were arranged by A.G.I.P. for members' wives and for members themselves when their otherwise arduous duties were over, and the Fondazione Ing. Lerici gave a cocktail party. The next meeting of the Association will be in Copenhagen in the late spring of this year.

MATHEMATICAL ASSOCIATION

ANNUAL MEETING

THE annual meeting of the Mathematical Association was held at King's College, London, during January 4-6, with the president, Prof. T. A. A. Broadbent (Royal Naval College, Greenwich), in the chair. In his presidential address, "Printer's Ink and the Teacher", Prof. Broadbent, who has edited the *Mathematical Gazette* since 1930, drew on this experience to offer two main suggestions to the teacher of mathematics. First, mathematics is a language, the

language of abstract, rational thought, and the teacher who wishes to train his pupils in this language must first be master of his own mother-tongue; good mathematics and clear, simple English go together. Secondly, the teacher must use periodical literature in mathematics to keep in touch with some part, however small, of current research, so as to be able to present school mathematics to his pupils as an essential element of a living, growing organism.

In the afternoon of January 4 the meeting discussed the report of the Association on the teaching of sixth-form geometry. The report recommends a first course, including all that can be regarded as suitable for every pupil who takes mathematics as a main subject after he begins to specialize in mathematics, science or engineering, and a second course, suitable only for mathematical specialists, in which the beginnings of abstract projective geometry could be studied, thus rendering less abrupt the transition from school geometry to university geometry. The discussion was opened by Prof. E. H. Neville (University of Reading), the chairman of the committee which drew up the report, and by Mr. H. Miller (Watford Boys' Grammar School). In the open discussion members recognized the high importance of the report, but suggested that some years would have to elapse before its recommendations could be digested and applied. In the evening of the same day, the principal of King's College, Mr. P. S. Noble, spoke on 'Euclid the Artist'. Mr. Noble, as a distinguished classical scholar, sees Greek geometry as an integral part of Greek thought and art, and, after sketching its growth from Thales to Apollonius, he compared mathematics with other typical products of the Greek genius, in its essential simplicity, logic and beauty. As a particular instance, a detailed comparison with Greek forensic oratory was drawn.

The proceedings on January 5 opened with a discussion between Mr. J. Kershaw (College of Building, Liverpool) and Dr. C. W. Jones (University of Liverpool) on 'Numerical Analysis'. Mr. Kershaw outlined a course in numerical analysis for engineers, and Dr. Jones commented on the points raised, the general content of the syllabus and details of method. This interchange of ideas proved very instructive, and the Association hopes to stage a more elaborate version of such a debate at a later meeting. Mr. O. T. Daltrey (Institute of Education, London) spoke next on 'Teaching through the Flash of Insight'. There is a logico-psychological conflict in the learning of mathematics, which may be resolved through teaching in accordance with Nunn's doctrine of the growth of mathematics from problem to process. 'Gestalt' psychology suggests that the problem must be seen as a whole, with a structure transcending the related parts; genuine learning ensues when this view of the problem leads to 'the flash of insight'. All teaching, said Mr. Daltrey, must be directed to the encouragement of individual insight and personal creative activity.

A discussion on 'Unified Mathematics as a Factor in Education' was opened in the afternoon of January 5 by Mr. K. R. Imeson (Sir Joseph Williamson's Mathematical School, Rochester), Miss W. A. Cooke (High School, Slough), Mr. K. B. Swaine (Yeovil School) and Miss K. M. Sowden (City of Bath Training College). 'Unified' mathematics may mean a combined course or a method of teaching. The speakers found the second aspect the more important, and suggested a number of topics which could be grouped around one fundamental mathematical

principle. Other matters of debate were the provision of combined or separate text-books, and the relevance of the method to pupils at different stages. In the open debate, details were criticized, but there seemed to be no definite verdict in favour of the 'unified' course.

The last paper was given by Dr. E. A. Maxwell (Queens' College, Cambridge), on 'The World Around Us', in which, by a survey of the "General Knowledge" questions set by the scholarship groups of the University of Cambridge during the past fifty years, he depicted the examiner as historian, artist and sociologist. Delicate textual criticism enabled Dr. Maxwell to make substantial contributions to the study of 'Examinio-Deuteronomy', 'Examinio-Genesis' and 'Examinio-Revelations'.

The president of the Association for 1954 is Prof. W. V. D. Hodge, Lowndean professor of geometry in the University of Cambridge.

BROADCASTING AND TELEVISION IN GREAT BRITAIN

AT the meeting of the Institution of Electrical Engineers on October 8, Mr. H. Bishop, director of technical services of the British Broadcasting Corporation, gave his inaugural address as president of the Institution for the current session. The major part of the address comprised a most useful and opportune review of the development of broadcasting and television with special reference to the services of the B.B.C., and to the need for international co-operation. While those engaged in most branches of engineering have much to gain by the exchange of information and experience with their contemporaries in other countries, the radio engineer has a special need for international agreement since radio wave propagation cannot be restricted to national boundaries.

In just over thirty years, broadcasting has been built up from nothing in all the important countries of the world; and several international organizations are now constantly concerned in seeking solutions to the problems which accompany the development and operation of home and overseas services. These problems include the allocation of frequencies in parts of the radio spectrum long since overcrowded, and the application of standardization to facilities for the exchange of programmes and the control of interference.

Some idea of the complexity of the problem of broadcasting on low and medium frequencies, on which most national home services at present depend, may be gathered from figures given by Mr. Bishop illustrating the growth of broadcasting in Europe. In 1929 there were two hundred stations in operation occupying a band-width of 1,014 kc./s.: as a result of a European Regional Conference at Copenhagen, a 'plan' came into operation in 1950 under which 243 stations were allocated frequencies which filled the total available band of 1,215 kc./s. Three years later, the number of stations in operation had increased by 50 per cent; and as a result, all stations, including those of the B.B.C. in Britain, are liable to suffer serious interference. An indication of the corresponding growth of world broadcasting is given by the fact that the total number of sound receivers in all countries rose from 20 million in 1929 to more

than 200 million in 1953; the latter figure corresponds to one receiver for every twelve persons in the world.

The dearth of frequencies and the continued increase in the number of stations present a serious problem in the maintenance of a home sound broadcasting service in the low- and medium-frequency bands; and there is little prospect of resolving this problem by an increase in power or improvement in aerial efficiency at transmitting stations. The high-frequency band (3-30 Mc./s.) is not suitable for local services, and now has its own very serious problems for external broadcasting to countries overseas. In pursuance of the present policy of the B.B.C. of providing for the national coverage of three sound programmes, it is therefore proposed to inaugurate home broadcasting services in the very-high-frequency band of 88-95 Mc./s. Considerable experience has been obtained by the B.B.C. in this band with an experimental station at Wrotham in Kent, erected in 1949; and it is now planned to build fifty-one stations at nineteen locations to provide for the Home, Light and Third Programme Services. The building of these new very-high-frequency stations will take several years, and additional transmitters may be added later to complete the national coverage.

With reference to television broadcasting, Mr. Bishop first reviewed the considerations that resulted in the decision to reopen, in June 1946, the London television station, which provided a regular public service from November 1936 until the outbreak of war in September 1939. This has resulted in the development of the television service in Britain on the basis of the pre-war transmission standards of 405 lines, with double interlaced scanning at a picture frequency of 25 per sec. In the light of developments since that time, there is no doubt that this was the right decision. The subsequent installation of additional high- and medium-power transmitters in the United Kingdom has been accompanied by technical developments which have enabled a steady and considerable improvement in picture quality to be obtained with the band-width limitations imposed generally by the radio and cable links between the television transmitters and the studio at which the programme originates. While the present plans of the B.B.C. are concerned with providing national coverage to the extent of 98 per cent of the population for a single programme, the Corporation has also under consideration the need for providing an alternative television programme on a nation-wide basis. Such alternative services, together with any competitive programme service the Government may decide to introduce, will have to be transmitted in various bands of frequencies between 174 and 960 Mc./s. A large amount of research on various aspects of the use of these frequencies is in progress in anticipation of such developments. It is in these bands, also, that any system of colour television will have to be accommodated. In this connexion, Mr. Bishop stressed the importance of ensuring that any colour system introduced must be compatible with the present black-and-white system. This means that the colour transmissions must be such that they provide for the reproduction of a black-and-white picture on the two and a half million receivers already in use in Britain, without any modification of the band-width or other features of these receivers. It may, of course, be necessary to add an adaptor to such receivers to enable them to be tuned to the transmissions in the higher-frequency bands; and

this and other matters are already receiving attention by those engaged in the radio receiver industry.

In the concluding portion of his address, Mr. Bishop referred to the fact that the rate of growth of membership of the Institution, which is about 38,000, appears to be decreasing. While this is not necessarily a bad thing, it might, he suggested, be associated with the problem of maintaining a sufficiency of recruits to the electrical engineering profession. He suggested that it is time to make a fresh assessment of the needs of the profession and the manner in which these could be met by stimulating the appropriate class of education in schools and universities.

NATIONAL RESEARCH DEVELOPMENT CORPORATION ANNUAL REPORT FOR 1952-53

THE report and statement of accounts of the National Research Development Corporation, covering the year ended June 30, 1953*, is the last which will appear before the Corporation's borrowing powers expire at the end of next June. Although the Development of Inventions Act, 1948, which established the Corporation, empowered the Board of Trade, with the consent of the Treasury, to make advances of up to £5 millions for the capital expenditure of the Corporation in connexion with the development and exploitation of inventions, only 10 per cent of that amount has been used by the Corporation for the development of new inventions during its first four years. A statutory function of the Corporation is to secure, where the public interest requires, the development or exploitation of inventions resulting from public research, and of any other invention which it appears to the Corporation is not being, or is being insufficiently, developed or exploited. Of the fourteen development projects currently in hand, five are derived from private sources. The great majority of the public inventions either require no development or are of such a character that industry, when interested, is prepared to accept the risk of development.

The activities of the Corporation in connexion with requests for assistance for development during the past four years thus suggests that within its statutory responsibilities the need for assistance is much less than was anticipated when the Corporation was established. As a result of these four years of working the Corporation is now a party to more than two hundred and fifty licence agreements with industry in the United Kingdom or abroad, and to revenue-sharing agreements with universities, university research workers and industrial research associations. The administration of 2,224 patents and patent applications in the United Kingdom and overseas thereby involved is a continuing commitment for the Corporation in respect of wasting assets with a maximum life of about sixteen years. The Corporation is also required to seek to recover its expenditure by licensing firms engaged in the industry concerned so as to use the inventions which the Corporation administers. Revenue from recurrent royalties has steadily increased, that for 1953 being £21,204, whereas that from paid-up royalties

* National Research Corporation. Report and Statement of Accounts for the Year 1st July 1952, to 30th June, 1953. Pp. ii+18. (London: H.M. Stationery Office, 1953.) 9d. net.

for premium royalties or options is necessarily irregular from year to year, and in 1953 was no more than £2,129 compared with £3,029 in 1950.

As regards development projects, electronic digital computers were still the largest single commitment. Commercial orders, including one for export, have been received for three of four large machines similar to that designed by Prof. F. C. Williams in the University of Manchester, and deliveries were scheduled to be made during 1953-54. The prototype of a smaller machine has been temporarily installed in the Mathematical Laboratory at Cambridge for trials. Development of the Packman potato harvester during 1952-53 was concentrated on the criteria necessary for a successful potato harvester as stated by the judges in the open competition of the Royal Agricultural Society of England. Development of the inventions in the field of hydrocarbon synthesis at the Imperial College of Science and Technology, London, proceeded without setbacks; but rapid progress was not at that time expected. Prototypes of a light steam-engine were being developed to suit the findings of a market survey in India and Pakistan. Development on both the aural microscope and the chick sexer was completed during the year, and a substantial number of chick sexers were sold in Britain and abroad.

Results of the pilot-scale production in East Africa of hecogenin from sisal juice have encouraged further contracts for supplies; the crude concentrate was being purified in the United Kingdom and pure hecogenin acetate was being made available for the synthesis of cortisone. Prototypes of the Burns inhaler for the administration of tritene and other volatile anaesthetics were about to be delivered for clinical trials. Resin-based formulations containing insecticides have been the subject of patent applications in the United Kingdom and of overseas and licence agreements made with several British paint manufacturers. Commercially produced formulations are becoming available on an increasing scale. Increased interest in a group of some thirty inventions in the plastic structures field, which originated in the Royal Aircraft Establishment, Farnborough, is attributed to growing realization of the importance of phenolic-impregnated asbestos felts as constructional materials, and polyurethane and furan resins for foams and adhesives, respectively. A special study of the process of shock-curing of plastic laminates was being carried through so that the results could be made available to industry, and the construction by the Corporation of a plastic structures demonstration laboratory was proposed. The prototype of a novel machine for the liquefaction of atmospheric gases on a scale considerably smaller than that of conventional machines, invented at the University of Reading, was being built, and a programme of development of a regenerative system of mechanical transmission, known as the 'Gyreasts' system, has been inaugurated. This is of particular application to public-service vehicles.

Of the 692 inventions communicated to the Corporation during the year, 273 were from Government departments and research councils, 6 from industrial research associations, 16 from Commonwealth official organizations, 48 from universities and 314 from British private firms and individuals. Of the 257 patents or patent applications, the assignment or transfer of which to the Corporation was registered during the year, 185 were from Government departments and research councils, 22

from industrial research associations, 36 from universities and 11 from British private firms and individuals. Of the Corporation's total holdings of patents and patent applications at June 30, 1953, 501 were United Kingdom granted patents and 498 United Kingdom patent applications, the corresponding overseas figures being 227 and 998, respectively.

IMPERIAL FORESTRY INSTITUTE, OXFORD

ANNUAL REPORT FOR 1951-52

THE annual report of the Imperial Forestry Institute, University of Oxford, for 1951-52* shows that the Institute has expanded beyond all recognition from its early beginnings at the inception of the late Lord Lovat, the first chairman of the Forestry Commission. The idea then, as it still is, was to give postgraduate courses to forestry graduates who had been nominated as forestry probationers by the Colonial Office, and to offer refresher courses to members of the Colonial Services on leave. This latter course was attended during the year under review by sixteen forest officers from Nigeria (five), Gold Coast and Tanganyika Territory (two each), and Sierra Leone, Northern Rhodesia, Uganda, British Guiana, Trinidad, Fiji and Sarawak (one each). In addition, an Indian forest officer (Bengal) and one Pakistani forest officer (Punjab) attended the course arranged for them. As evidence of the wide nature of the courses offered at the Institute, five forest officers (Gold Coast, Nigeria, Trinidad and Sudan) attended a special aerial survey course during the Michaelmas term. In addition, the silviculturist from the Agricultural Research Institute, Wad Medani, Sudan, and a German student from the forestry school of Göttingen attended the Institute for periods. It is of interest and importance to learn that nine students successfully sat the Final Honours School of Forestry. Of these, one Ceylon scholar took up a post in his country, another Gold Coast scholar took a post in the Gold Coast Forest Service, a third forestry scholar has returned to Uganda and two of the others obtained posts in the Colonial Forest Service.

The importance of the wide departure from the original conception of the Institute may lie in the future with the changing administrative policies in the British Colonies. Although little alluded to, forestry must play an important part if the forest services are eventually to be managed by the native administrations concerned. It is not possible, at present at any rate, to train fully the officers required for the higher forestry administrative posts in the Colonies. A final course in Europe may be regarded as indispensable to study European forest management which has been in force for so long a period. At the Institute such advantages are provided and other facilities are available to give the final training. For this reason alone the future importance of the Institute cannot be too strongly emphasized. The report deals fully with the various lecture courses given and the practical courses in the forests of France, Switzerland and Denmark, and also in Great

* The Imperial Forestry Institute, University of Oxford. Twenty-eighth Annual Report 1951-52. Pp. 23. (Oxford: Holywell Press, Ltd., 1953.)

Britain in both Forestry Commission areas and on private estates. Advantage can be taken of courses in every branch of forestry, including saw mills and utilization generally, soil science and other research.

The staff of the Institute, excluding the office and library members, now numbers fifteen, including Prof. H. G. Champion, the head of the Institute, with five others from university departments who assist in instructional work. An excellent reproduction of a drawing of the Institute building, by Alan Course of the *Oxford Mail*, is given as a frontispiece.

PRECAUTIONS IN THE USE OF IONIZING RADIATIONS IN INDUSTRY

THE Factory Department of the Ministry of Labour and National Service has produced an important and interesting booklet which gives a clear warning to the industrial worker using X-rays or the radiations from radioactive substances of the potential hazards and dangers to which he is exposed and of the precautions he needs to take to protect himself*. At the same time it illustrates the wide and rapid spread of the use of these radiations in industry for the examination, testing and improvement of products and processes. In the introduction to the booklet the numerous applications are outlined. These cover X-ray radiography of metals; X-ray fluoroscopic examination of manufactured articles; X-ray diffraction analysis of crystalline compounds; gamma radiography; elimination of static electricity; thickness control and measurement; and radioactive tracer methods to elucidate the mechanism of chemical, physical, engineering and biological processes. It is stated that no industrial processes coming under the Factories Act have as yet been reported in which neutrons, protons and deuterons, which are biologically very dangerous radiations, have been used; but the possibility that these particles may soon find suitable applications, particularly neutrons for radiography and diffraction, cannot be excluded.

It is emphasized in the section dealing with health hazards that experience so far shows that, with proper forethought and care, risks of impairment of the health of work-people in factories where ionizing radiations are used can be countered; but that complete immunity from harmful effects depends on an intelligent appreciation of the properties of the various radiations and of their potential damaging effects on the human body, and on vigilant attention being paid to the necessary precautions. This seemingly calls for specially and technically trained staff; in fact, to appreciate fully the detailed and valuable information given in the booklet the reader must have more than a nodding acquaintance with the terminology of radiation physics and chemistry.

In another section recommended maximum permissible dosage-rates, based mainly on the internationally agreed values adopted at the Sixth International Congress of Radiology 1950, are quoted and explained, and the latter half of the booklet is devoted to recommended precautions, both of a general nature and when using particular apparatus

or methods. Under the heading of general precautions, the following categories are dealt with: planning and equipment; inhalation and ingestion precautions; supervision, training and monitoring; flow or dosimeter tests of workers' radiation exposures; and medical supervision. Special precautions are discussed separately for X-radiography, X-ray fluoroscopy, X-ray crystallography, gamma radiography, radioactive static eliminators, thickness gauges, radioactive tracer work and the handling of unsealed radioactive materials. The booklet ends with a valuable comprehensive bibliography of published memoranda on radiological hazards and protection.

The Factory Department of the Ministry of Labour and National Service is to be congratulated on the production of such an informative and timely booklet; it is a work which boldly presents the dangers of the new and powerful methods but yet, by indicating to industrialists how adequate precautions can be taken to safeguard their workers, wisely advocates the introduction and expansion of the use of ionizing radiations in industry.

ISOLATION AND PROPERTIES OF ALPHA-CORTICOTROPIN* FROM SHEEP PITUITARY GLANDS

By PROF. CHOH HAO LI, IRVING I. GESCHWIND, ANTHONY L. LEVY, J. IEUAN HARRIS, JONATHAN S. DIXON, NING G. PON and JERKER O. PORATH

Hormone Research Laboratory, Department of Biochemistry, University of California, Berkeley

IN an earlier communication¹ we described the preparation of a highly purified ACTH fraction (*E*) from an acid acetone extract of sheep pituitaries. We wish to report herewith the isolation from fraction *E*, without pepsin digestion, of a peptide (α -corticotropin) which behaves as a pure substance. This hormone is clinically active, and possesses adrenal-stimulating activity according to the results of standard bioassay procedures for adrenocortical function. While this work was in progress, the isolation and properties of corticotropins *B* and *A* from pig glands was reported by investigators from the Merck² and the Armour³ laboratories, respectively.

The first step in a typical isolation of α -corticotropin is the precipitation at pH 9.3-9.4 of inactive material from a solution of fraction *E* in 50 per cent dioxane. The supernatant obtained from this step is further purified by zone electrophoresis on starch⁴. An electrophoretic pattern obtained in this manner is illustrated in Fig. 1. The active fraction is eluted from segments 6-7 and then chromatographed on 'Amberlite XE-97' resin under the conditions shown in Fig. 2. The contents of tubes 34-49 are combined, desalted, and submitted to 100 transfers in the all-glass counter-current distribution apparatus of Craig and Post⁵ using a 2-butanol/0.5 per cent trichloro-

* In accordance with the suggestion of the Merck² and Armour³ groups in designating pepsin-hydrolysed pig ACTH as corticotropin *B*, and the unhydrolysed hormone as corticotropin *A*, we have chosen to designate unhydrolysed ACTH obtained from sheep pituitaries as α -corticotropin, since many of its chemical and physicochemical characteristics differ from those described for corticotropin *A*.

acetic acid system (Fig. 3). The material in those tubes falling within the theoretical distribution curve for a partition coefficient of 3.20 is again desalted, and re-distributed (fifty transfers) in a 2-butanol/0.1 per cent trichloroacetic acid system (Fig. 4). Tubes 10-21, the contents of which follow the theoretical distribution curve for a partition coefficient of 0.41, yield α -corticotropin, which behaves as a single substance as judged by the following additional criteria of purity.

(a) *Zone electrophoresis*. Zone electrophoresis on starch at pH 7.0, 8.2, 9.1, 10.2 and 11.2 shows that α -corticotropin migrates as a single zone which contains the ACTH activity. (b) *Chromatography*. Elution analysis of α -corticotropin on 'XE-97' resin with 0.08 M sodium bicarbonate gives a single peak. (c) *Carboxyl end-group analysis*. When α -corticotropin is treated with carboxypeptidase, a single C-terminal amino-acid, phenylalanine, is released. Kinetic experiments show further that phenylalanine, glutamic acid and leucine are released successively in amounts approaching equimolar proportions. These results suggest that α -corticotropin is composed of a single peptide chain, terminating in the sequence ... leu.glu.phe. (d) *Chemical composition*. Amino-acid analyses of different preparations of α -corticotropin are consistent with the view that the product is a single chemical species. (e) *Biological assay*. Assay of the hormone in hypophysectomized rats

Fig. 2. Chromatography on 'XE-97' resin (Na form) of material obtained from zone electrophoresis; 10 ml. per tube. The hormonal activity is located in tubes 34-49

Fig. 3. Counter-current distribution (100 transfers) of material obtained from chromatography on 'XE-97' resin. System: 2-butanol/0.5 per cent aqueous trichloroacetic acid

Fig. 4. Counter-current distribution (50 transfers) of α -corticotropin. System: 2-butanol/0.1 per cent aqueous trichloroacetic acid

reveals no evidence of contamination with either thyrotropin, somatotropin or gonadotropin; the local test in pigeons shows the absence of prolactin activity. Bioassay for melanophore-expanding activity in hypophysectomized *Rana pipiens* indicates that α -corticotropin possesses an intermediate contamination of less than 0.1 per cent. The adrenal-stimulating activity as estimated by the adrenal ascorbic acid depletion method⁶ is approximately 150 I.U. per mgm. In hypophysectomized rats, injection of the preparation in beeswax-peanut oil suspension⁷ causes hypertrophy of the adrenal cortex, as judged by histological changes and by adrenal weight increment.

The molar ratio of amino-acids in α -corticotropin is as follows: alanine 3, arginine 3, aspartic acid 2, glutamic acid 5, glycine 3, histidine 1, leucine 1, lysine 4, methionine 1, phenylalanine 3, proline 4, serine 3, tryptophan 1, tyrosine 2 and valine 3. Tyrosine and tryptophan were estimated spectrophotometrically⁸, while the other amino-acids, including tyrosine, were estimated by quantitative paper chromatography of their dinitrophenyl derivatives⁹. The minimum molecular weight of α -corticotropin, computed from these analytical data, is approximately 4,500. A similar value may also be

calculated for the equivalent weight if it is assumed that one mole of phenylalanine is released per mole of peptide by the action of carboxypeptidase. The isoelectric point of α -corticotropin, estimated from zone electrophoresis on starch, is found to be pH 7.0.

It is of interest to note that certain properties of α -corticotropin are different from those reported for corticotropins A and B. For example, all three preparations differ markedly in amino-acid content^{10,11}; furthermore, the partition coefficient of corticotropin A in a 2-butanol/0.2 per cent trichloroacetic acid system is 1.82¹², whereas that of α -corticotropin in the same system is 0.75. On the other hand, the C-terminal tripeptide sequence in α -corticotropin is identical with that reported for corticotropin A¹⁰, and both preparations possess comparable ascorbic acid depleting potencies.

This investigation was aided in part by grants from the U.S. Public Health Service and Eli Lilly and Company. We also wish to acknowledge the generous support of Merck and Co. and the Armour Laboratories during the early stages of this investigation. [Nov. 27.]

EFFECTS OF ALPHA-(1-NAPHTHYLMETHYLSULPHIDE)-PROPIONIC ACID ON THE GROWTH OF EXCISED TOMATO ROOTS

By DR. H. E. STREET

Department of Botany, University of Manchester

EARLIER work¹ has shown that the main axis meristems of excised tomato roots function only for a limited time when the roots are grown in constantly renewed modified² White's medium. This medium is of favourable pH, contains an adequate concentration of all the necessary nutrients and will promote over a prolonged period a high rate of increase in fresh root weight. The main axis, however, ceases to increase in length while the lateral roots are still growing rapidly. Further increase in fresh weight is then due to the growth of first-order laterals; at a later stage it is dependent upon the activity of second- and third-order lateral meristems. The duration of meristematic activity in individual root tips can be prolonged by repeatedly excising

them from the root systems to which they have given rise³. This survival of activity in meristems excised at regular intervals can be further prolonged by low-intensity illumination of the cultures⁴. It is decreased by increasing the sucrose concentration in the medium⁵ or by additions of β -indolylacetic acid (IAA) even at non-inhibitory concentrations⁶.

On this and other evidence the hypothesis has been advanced⁷ that the level of meristematic activity in roots is controlled by a hormone which at low concentration stimulates and at high concentration inhibits growth. Irreversible loss of meristematic activity is considered to result when the concentration of this hormone reaches a critical supra-optimal level. This hormone, or some precursor of it, is considered to be synthesized in the older parts of the root and transported to the main apex. It is postulated that a sub-optimal concentration of this hormone in the newly initiated meristem continuously increases as, during culture, the root system derived from the meristem increases in size.

The above hypothesis was supported by the findings that the response of root meristems to α -(1-naphthylmethylsulphide)-propionic acid (NMSP)⁸ changed during culture and that survival of meristems, subcultured in medium of high sucrose content, was enhanced by NMSP-treatment⁹. This substance, which conforms to McRae and Bonner's¹⁰ criteria for anti-auxins, was shown by Åberg¹¹ to antagonize the inhibition of seedling root growth by 1-naphthaleneacetic acid, by 2:4 dichlorophenoxyacetic acid and to a lesser extent by β -indolylacetic acid.

A study has now been made of the effects of NMSP on the growth of excised tomato roots (clone of Sutton's Best-of-All) in large volumes of medium (1,000 ml. per root). Modified White's medium in which iron (1.4 p.p.m.) was supplied as ferric citrate instead of as sulphate was used. Each flask was inoculated with a single 10-mm. root tip and incubated at 27° C. On the ninth day of culture a filter-sterilized, concentrated solution of NMSP was used for establishing in the medium concentrations ranging from 0.25 to 1.0 mgm./l. Roots were harvested after thirty-one days, by which time all roots, with the exception of some of those receiving 1.0 mgm./l. NMSP, had ceased main axis growth. Mean values for main axis lengths are shown in the accompanying table. The characteristic morphology of the control and NMSP-treated roots is illustrated by the accompanying photographs of representative roots.

At all NMSP concentrations the duration of main axis growth was prolonged beyond that of the controls. At 0.25 and 0.50 mgm./l., linear growth-rate of the main axis was initially increased, at higher concentrations decreased. During the first few days after its addition, 1.0 mgm./l. was clearly inhibitory

MAIN AXIS GROWTH OF EXCISED TOMATO ROOTS DURING 31 DAYS OF CULTURE

No. of cultures	Mgm./l. NMSP added on the ninth day of culture	Mean values for increase in main axis length (mm.) $\pm$ standard errors
10	Nil	171 $\pm$ 10
7	0.25	275 $\pm$ 15
6	0.50	305 $\pm$ 12
6	0.75	372 $\pm$ 26
8*	1.0	422 $\pm$ 28

* Three roots the main axis length of which did not exceed the mean value for controls were omitted in calculating mean and standard error.

Photographs of representative control and NMSP-treated roots

and in some cases the main axis meristems did not survive this period. Excluding these roots (see footnote to the table) it was found that increase in NMSP concentration up to 1.0 mgm./l. caused a progressive increase in the average values for total main axis growth. At 0.50 and particularly at 0.25 mgm./l., growth of first-order lateral meristems was not inhibited and the duration of their growth was prolonged. This enhancement of lateral growth was most marked where only a limited extension of main axis growth occurred. At the higher NMSP concentrations, particularly at 1.0 mgm./l., lateral growth was checked. Youngest laterals were inhibited most strongly.

The effect of NMSP described above can be interpreted on the basis that it acts by antagonizing a natural hormone present in the root meristems. The higher concentrations are considered to induce a sub-optimal effective hormone-level in the meristems, thereby lowering the growth-rate but most effectively prolonging the duration of activity of individual meristems. The lower concentrations are considered to reduce the supra-optimal hormone concentration, developed during the first nine days of culture, to one nearer, but still probably above, the optimum. They therefore increase growth-rate but are less effective in prolonging the duration of meristematic activity. Lateral meristems, having a lower hormone content than the main axis meristems, are almost completely inhibited by NMSP concentrations which permit main axis growth. Cessation of main axis growth in the control roots and in roots treated with the lower concentrations is considered to result from the development, as growth proceeds, of a critical supra-optimal hormone concentration; inhibition of lateral growth in high NMSP concentration is regarded as due to a lowering of the effective hormone concentration in the lateral meristem to a critical sub-optimal level.

Elsewhere⁴ it has been shown that β -indolylacetonitrile (IAN), at concentrations causing up to 50 per cent inhibition of main axis growth, does not markedly affect the duration of activity of meristems repeatedly subcultured. Evidence has also been obtained that the effects of NMSP on meristematic activity cannot be explained in terms of an NMSP-IAA antagonism⁴. The view is therefore advanced

that a natural hormone, other than β -indolylacetic acid or β -indolylacetonitrile, controls the activity of excised tomato root meristems grown under our conditions of culture. This emphasizes the interest which will be attached to studies involving the other growth regulators the presence of which in roots has been revealed by recent chromatographic work⁴.

A LARGE HIGH-PRESSURE ULTRAFILTER

By J. J. BULLEN, C. THURLBOURN and P. BROWN
Department of Animal Pathology, University of Cambridge

ULTRAFILTRATION is a useful technique for concentrating weak solutions of proteins. The process is essentially simple and should avoid the partial loss of material frequently incurred by the use of chemical methods. Unfortunately, the rate of concentration is often too slow to be of much value, especially with labile material.

An ultrafilter has been designed for the rapid concentration of bacterial toxins and might be found useful in other fields where highly concentrated solutions of proteins are required. The apparatus has a total capacity of 15 litres and a filter area of 400 sq. cm. Ultrafiltration through a collodion membrane is carried out under nitrogen at a pressure of 300 lb. per sq. inch. The membrane is supported on a flat smooth porous tile, which in turn rests on a perforated steel plate. The ultrafiltrate is collected in a flask beneath the filter.

Construction. The filter consists of a cylinder of $\frac{1}{2}$ -in. mild steel, 12 in. high, 9 $\frac{1}{4}$ in. internal diameter. Two flanges, one at the top, one at the bottom, each 1 $\frac{1}{2}$ in. wide, are tapped to receive sixteen $\frac{1}{4}$ -in. bolts

Fig. 1. 1, Flange. 2, Rubber washer. 3, Collodion membrane. 4, Porous tile. 5, Rubber ring. 6, Metal washer. 7, Perforated base plate. 8, Bolt.

which secure the lid and base plate. The lid of $\frac{1}{4}$ -in. steel is drilled to accommodate a pressure gauge, a safety valve, a release valve and an inlet valve bearing a union for the nitrogen pipe. Between the lid and the rim, which are both grooved, an $\frac{1}{4}$ -in. rubber washer is fitted.

The construction of the bottom of the apparatus is shown in Fig. 1. The base plate (7) of $\frac{1}{4}$ -in. steel is drilled with nine concentric rings of holes 0.1 in. in diameter and half an inch apart. The porous tile (4) of white unglazed porcelain, ground flat on both sides, is approximately $\frac{1}{8}$ in. thick. Tightening the bottom bolts presses the edge of the membrane (3) between the tile (4) and a rubber washer $\frac{1}{4}$ in. thick (2) resting on a grooved flange (1); this provides a leak-proof seal. The rubber washer is compressed to about half its thickness; this allows some latitude in the thickness of the tile. Excessive pressure on the tile is prevented by the metal washer (6). The bolts were screwed up as tightly as possible. A hard rubber ring (5) which projects from a rectangular groove prevents any leakage of ultrafiltrate. The whole apparatus is tin-plated to prevent corrosion.

Preparation of the Membrane. A sheet of 'Cellophane' (British Cellophane, Ltd., P.T. 300) is stretched over a square of plate glass and fixed to the under-side with 'Cellotape'. The glass sheet is placed on a tray, 'Cellophane' surface uppermost, and an 8 per cent solution of collodion in glacial acetic acid (I.C.I.) is poured on to it. When the surface has been covered the glass is picked up with the aid of rubber gloves and drained from each corner in turn until most of the surplus collodion has been removed. It is then plunged into cold water. After a few minutes the 'Cellophane' sheet can be cut away from the edge of the glass. The collodion membrane can then be separated easily from the 'Cellophane' sheet. It is allowed to harden in running water over-night. After hardening, the membrane is found to have one smooth surface and the other slightly uneven, and it is placed on the tile smooth side upwards and trimmed to fit. Two litres of 0.5 per cent solution of sodium bicarbonate are then forced through the membrane under a pressure of 100 lb. per sq. in. to remove any traces of acid.

Six membranes prepared in succession by this method have all proved to be satisfactory.

Performance. Under a pressure of 300 lb. per sq. in., the bicarbonate solution passed through the membrane at the rate of approximately 10 litres an

hour. At the same pressure, 2 litres of a solution of horse haemoglobin in distilled water (40 mgm. per 100 ml.) were reduced practically to dryness in $2\frac{1}{2}$ hr. The haemoglobin remained on the surface of the membrane as a thick film, too dry to flow. 3 ml. of the ultrafiltrate gave no reaction to the benzidine test. 3 ml. of a 1/5,000 dilution of the original haemoglobin solution gave a positive reaction. This showed that less than 1/5,000 part of the haemoglobin had passed through the membrane.

In five successive tests no haemoglobin was detected in the ultrafiltrate. On three of these occasions a hand spectroscope was used, on two the benzidine test. On another occasion 1,200 ml. of papain digest broth containing *Olostridium welchii* epsilon toxin was reduced in $2\frac{1}{2}$ hr. to approximately 10 ml. of fluid which had the consistency of treacle. The ultrafiltrate was non-toxic; but the 'treacle' was intensely toxic.

To maintain rapid rates of filtration it was necessary to rock the apparatus gently to and fro every 15 min. to avoid premature accumulation of highly concentrated material on the surface of the membrane. This could probably be avoided by the incorporation of some form of stirrer.

The pressure fell during filtration by about 10 lb. every 30 min. This was of little importance with small volumes. For prolonged filtration it is hoped to fit an automatic release valve to keep the pressure constant at 300 lb. per sq. in.

The apparatus was made by Messrs. D. Mackay, Cambridge, and the tiles by Messrs. James Macintyre and Co., Ltd., Burslem. We owe thanks to many for useful suggestions, especially Mr. J. Welch, of Messrs. D. Mackay, and Mr. H. Proom, of the Wellcome Research Laboratories. [Oct. 21.]

CRYSTALLINE SWELLING OF MONTMORILLONITE

Use of Electrolytes to control Swelling

HOFMANN, ENDELL AND WILM¹ first demonstrated that montmorillonite had a layer structure similar to mica but differed from it in that the interlayer distance was variable and dependent on water content. Many workers²⁻⁴ have since verified this one-dimensional crystalline swelling and have shown that the exchangeable cations, situated between the silicate sheets, are largely responsible for swelling. Initially, swelling is a result of hydration of the cations⁵; but later it proceeds in 3-A. steps⁶. All the above workers are in agreement that with calcium-montmorillonite the interlayer swelling does not proceed beyond 20 Å., but Mering⁷ and Barshad⁸ failed to confirm the report of Hofmann *et al.*¹ that sodium-montmorillonite gave a spacing very much greater than 30 Å. in water. This record is probably to be interpreted as failure to observe a definite diffraction line up to the low-angle cut-off of the camera. Mering concluded that crystalline swelling ceased at 20 Å., when the (001) spacing became very diffuse.

In contrast to its observed crystalline swelling, sodium-montmorillonite will swell to twenty times its own volume in water⁹. Also in contrast to the limited crystalline swelling are the physico-chemical measurements on sodium-montmorillonite^{9,10}, which suggest that in suspensions and gels the particles are the fundamental silicate sheets, 10 Å. thick.

During work by one of us (J. P. Q.), with Dr. R. K. Schofield, on the permeability of clays to electrolytes, it became desirable to know the (001) spacing of montmorillonite in sodium chloride and calcium chloride solutions of various concentrations. X-ray diffraction measurements made on montmorillonite while immersed in these solutions are given in the accompanying table.

(001) SPACING OF SODIUM-MONTMORILLONITE IMMERSED IN SODIUM CHLORIDE

NaCl normality	$d_{(001)}$ (in Å.)
4	15.4
1	18.7
0.5	19.0
0.01	40

(001) SPACING OF CALCIUM-MONTMORILLONITE IMMERSED IN CALCIUM CHLORIDE

CaCl ₂ normality	$d_{(001)}$ (in Å.)
8	15.8
2	18.7
0.2	19.0
water	19.0

The observation of a definite spacing at 40 Å. is of interest as it indicates that crystalline swelling can proceed beyond 20 Å. The results also show that electrolytes can be used as a convenient means of controlling swelling in the range of high water content.

Mering⁷ has shown that almost all the macroscopic swelling of montmorillonite takes place at water contents equivalent to a relative humidity of greater than 99 per cent. To control the water content and measure the X-ray spacing in this range by direct methods would involve very precise temperature control.

This work was carried out at Rothamsted Experimental Station, Harpenden, Herts, during the tenure, by both authors, of C.S.I.R.O. (Australia) studentships.

Manner of Swelling of Montmorillonite

THE use of electrolytes as a means of controlling the swelling of montmorillonite was so convenient that a study was made of the variation of (001) spacing with electrolyte concentration for montmorillonite saturated with the following cations: $H^+(H_2O^+)$, Li^+ , Na^+ , K^+ , NH_4^+ , Ca^{++} , Mg^{++} , Cu^{++} , Ba^{++} , $Cu(NH_3)_4^{++}$, Al^{3+} .

An oriented flake¹ of sodium-montmorillonite (Wyoming bentonite) about 0.03 mm. thick was placed in a plastic tube of 0.3 mm. internal diameter. The flake was saturated with the desired cation by passing a strong (1–4 *N*) salt solution through the plastic tube. Then a solution of the same salt at the required concentration was passed through the tube

and finally the ends of the tube were sealed, keeping the flake immersed in the salt solution. Except where otherwise stated, the salts used were chlorides.

A diffraction pattern of the oriented flake, immersed in the salt solution, was obtained by using a curved crystal monochromator which had been modified so that spacings up to 400 Å. could be recorded on a flat film placed at the focus. Copper $K\alpha$ radiation was used.

For (001) spacings up to 22 Å., the (001) diffraction lines were relatively sharp and formed a rational or irrational series. For (001) spacings of greater than 30 Å., the (001) diffraction lines became diffuse with only one or two orders visible to the eye. Although the (001) line could easily be measured visually, these diffraction patterns were microphotometered and interpreted using a one-dimensional Fourier transform method².

According to their effect on the swelling of montmorillonite the cations may be grouped as follows.

H^+ , Li^+ : in 4 *N* solutions, the (001) spacing was 15.4 Å. With decreasing concentrations, the (001) spacing increased, giving a rational series of (001) lines at 19 Å. and 22.5 Å., indicating that the expansion was stepwise. At 0.5 *N* the spacing jumped from 22.5 Å. to 36 Å. and the diffraction pattern became diffuse. The interlayer spacing then increased continuously, being linear with respect to $1/\sqrt{N}$, so that at 0.01 *N* the spacing was about 140 Å. The diffuse nature of the diffraction pattern prevented observations beyond this point with the equipment available.

Experiments with acid-montmorillonite had to be completed within several hours of bringing the montmorillonite into contact with hydrochloric acid, as after this time the spacing changed. In concentrations of less than 0.5 *N* hydrochloric acid the spacing collapsed to 22.5 Å. within a day. This change is almost certainly due to acid attack on the clay releasing Al^{3+} ions³, and it is consistent with the anomalous swelling properties of acid-montmorillonite⁴.

Na^+ : In sodium chloride the montmorillonite departed from the above behaviour in that stepwise swelling proceeded only to 19 Å. and then, at 0.3 *N*, the spacing jumped to 40 Å. In more dilute solutions it followed the same line as H^+ and Li^+ . The variation of the interplanar spacing with $1/\sqrt{N}$ for sodium chloride solutions is shown in Fig. 1.

Fig. 1. Lattice expansion of sodium-montmorillonite in sodium chloride solutions

Fig. 2. Lattice expansion of sodium-montmorillonite as a function of water content

In sodium sulphate solutions swelling proceeded in the same manner, the spacings being the same as those of more dilute sodium chloride solutions.

Experiments with hectorite, from Hector, California, U.S.A., and montmorillonite, from Redhill, England, indicated that in sodium chloride solutions their behaviour was similar to that of Wyoming montmorillonite.

K^+ , NH_4^+ , Ca^{++} : The spacing of montmorillonite saturated with these cations normally did not proceed beyond 15 Å., even in water. However, by expanding the montmorillonite in sodium chloride and then replacing the sodium ions by potassium ions, using weak potassium chloride solutions, large spacings were obtained with potassium-montmorillonite. Ammonium-montmorillonite behaved in the same way.

Mg^{++} , Ca^{++} , Be^{++} , Al^{++} : With these ions the spacing increased from 15 Å. to a maximum of 19 Å. with decreasing concentration.

$Cu(NH_3)_4^{++}$: Montmorillonite saturated with this ion gave a spacing of 12.4 Å. which was independent of electrolyte concentration.

Fig. 2 shows the results obtained by adding known amounts of water to sodium-montmorillonite. It is evident that, within experimental error, which is largely due to the difficulty of maintaining equilibrium at such high relative humidities, most of the swelling of montmorillonite can be accounted for by lattice swelling. Between water contents of 0.37 and 1.19 gm./gm. clay, both 19-Å. and 40-Å. spacings are present, the former decreasing in number and the latter increasing with increasing water content. The 40 Å. spacing gives a diffuse second-order diffraction line at 20 Å., so that while the water content increases by three times the 19-Å. line shifts very little in position but becomes diffuse. It was this behaviour that led Mering⁵ to conclude that the interlayer distance did not increase beyond 20 Å.

The above results suggest that the swelling of montmorillonite takes place in two rather distinct ways. First, below 22 Å. the interlayer expansion is stepwise⁶ and very dependent on the exchangeable cation⁷. For the monovalent cations the number of

water layers taken up is directly related to the hydration energy of the cation. Secondly, after the jump to greater than 35 Å., where it occurs, the expansion is continuous and independent of cation for monovalent cations. In this region the montmorillonite is probably developing a diffuse double layer and behaving as a colloid⁸. The swelling is then essentially osmotic and is expected to be independent of cation for ions of the same valence.

The sudden jump in spacing from about 20 Å. to about 40 Å. is interesting and is probably associated with reversal of the force due to the charge on the montmorillonite sheets. At low spacings the force will be electrostatic and attractive, as in mica, whereas at high spacings the charge will result in a repulsive (osmotic) force⁹.

At high spacings this repulsive force is presumably balanced by van der Waals-London attractive forces⁷.

For the swelling to pass from the first to the second region the hydration energy of the monovalent interlayer cations must be sufficient to expand the spacing to about 20 Å., that is, to overcome the electrostatic attraction. The hydration energy of the large monovalent cations is insufficient to overcome this potential barrier, so that when collapsed, montmorillonite saturated with these cations cannot expand beyond about 15 Å. However, if this barrier is overcome by some other means, then the montmorillonite can continue to expand. This behaviour is consistent with the observation of Mattson¹⁰, who noted that Sharkey soil colloid, a montmorillonite, swelled greatly when saturated with potassium ions but not after drying.

Why the divalent ions with their greater hydration energy do not cause greater expansion is not clear. However, several factors will contribute to limit their swelling. Because divalent ions have a much larger sphere of dielectric saturation, the electrostatic attractive forces between neighbouring montmorillonite sheets will not diminish as rapidly as they do for monovalent ions. In addition, the theory of Langmuir¹¹ indicates that the osmotic repulsive force will be much less for divalent ions, and montmorillonite sheets separated by large distances (greater than 25 Å.) will collapse together if this force is insufficient to counterbalance the van der Waals attractive forces.

A full account of this work will be published elsewhere. It was carried out at Rothamsted Experimental Station, Harpenden, Herts, during the tenure of a C.S.I.R.O. (Australia) studentship.

Temperature Distribution within the Earth's Core

IN view of the recent article by Prof. F. E. Simon in *Nature* on the melting of iron at high pressures¹, it seems desirable to review the hypothesis I put forward to account for a solid inner core within the earth².

At the boundary between the silicate mantle and the iron core there must be a discontinuity in the melting-point-depth curve, although the actual temperature must be continuous across the boundary. The form of this discontinuity could, mathematically, take any of the three cases shown in Fig. 1. Case (i), in which the melting-point curve in the core is always above that in the mantle, is impossible; for the actual temperature curve must lie below the melting-point curve in the mantle, above the melting-point curve in the core, and yet be continuous across the boundary. Cases (ii) and (iii) are both possible. In case (ii), the melting-point curve in the core never rises above the value of the melting point in the mantle at the core boundary, and in case (iii) it exceeds this value for part of the core. If case (ii) is the truth, then as the earth cooled from a molten state, the entire core would be left liquid, whereas if case (iii) is the truth, then I have shown that a solid inner core would be formed². As the earth cooled still more, the mantle would begin to solidify from the inside outwards, trapping a liquid layer between it and the now solid inner core. The above arguments can be modified if the earth were formed by the cold accretion of dust particles and afterwards heated up. If the earth became completely molten, its subsequent history would be the same as that already discussed. On the other hand, if the earth is still heating up, then either case (ii) or case (iii) could lead to a liquid core with a solid inner core.

However, most advocates of a cold origin for the earth consider the earth as relatively homogeneous at the beginning and to have differentiated as it heated up (see, for example, Urey³). The energy produced in the formation of the iron core, approximately 2×10^{28} ergs, would be released as heat near the core and would thus keep temperatures so high that a solid core would be impossible unless the earth had become entirely molten and all differentiation taken place, its subsequent history being the same as that of an earth with a hot origin. Finally, Rosenblatt⁴ has considered the effect of a probable primeval endowment of uranium-236 and shown

Fig. 2

that, owing to the relatively enormous disintegration-rate of this element, even a cold earth would have become completely molten. For these reasons, therefore, the rest of this communication is confined to the case of an earth cooling from a molten state.

Cases (ii) and (iii) can now be examined in the light of the work of Prof. Simon¹. There are few data available on the melting point of silicates at the high pressures that prevail near the core boundary. The recent work of Uffen⁵ based on seismic data and the theory of the solid state indicates that the melting point in the mantle at 2,900 km. is about 5,000° K. Unless there has been considerable cooling of the mantle, this would favour case (ii), that is, an all-liquid core, since the melting point of iron even at the centre of the earth is less than 4,100° K.¹ However, such a large difference in the two melting points seems unlikely. The earlier work of Daly⁶ gives a melting-point temperature of about 4,000° for the mantle at 2,900 km., which indicates that case (iii), that is, a solid inner core, is possible. Indeed, if this is the truth, as seems most likely from seismic evidence, it is possible to calculate the actual temperature at the core boundary by using the adiabatic temperature gradient curve for the core as obtained by me².

Since the boundary *B* of the inner core is the point of transition between the liquid and solid state in the core, the melting point at *B* must be the actual temperature at that level. Hence, by extending the adiabatic curve back from this point to *A*, the boundary between the core and mantle, we can obtain the actual temperature at *A* (see Fig. 2). The actual temperature at *A* must be less than the melting point of the silicates that compose the mantle and above the melting point of iron. Taking Prof. Simon's¹ value of the melting temperature at *B* as 3,900° K., the actual temperature at *A* is 3,800° K.

Finally, it is possible to obtain an upper limit for the melting point of the mantle at the core boundary by calculating the adiabatic curve that passes through *C*, the melting point at the centre of the earth. The melting-point curve of the mantle must be below this curve, or a solid inner core could not have formed. Prof. Simon's value for the melting point at *C* is 4,040° K., and this leads to the upper limit to the melting point of the mantle at 2,900 km. as 3,880° K. Prof. Simon places an upper limit of 4,880° K. for his temperature at *C*, and this in turn would raise

Fig. 1. Possible forms of the melting-point-depth curve in the neighbourhood of the core boundary

the upper limit to the melting point of the mantle at the core boundary to 4,000° K.

RECENTLY, Simon¹ has presented a method of estimating the melting-point temperature of iron at high pressure. This is of considerable geophysical interest as it is frequently argued that the earth's core is composed of iron². A method of estimating the melting-point temperature in the mantle had been proposed previously by Uffen³; but no reliable method of estimating this value in the core was then available. These two results are combined in Fig. 1, the dotted lines indicating our estimated limits of error. This curve is very similar to that given by Jacobs⁴ in his qualitative explanation for the existence of a solid inner core to the earth. Furthermore, it provides an upper limit of 5,000° K. and a lower limit of 3,000° K. for the temperature at the core-mantle boundary. These two observations provide a basis for discussing the plausibility of some of the theories of the constitution and history of the earth's interior.

In Jacobs's explanation of the solid inner core, it is necessary to postulate a discontinuous decrease in the melting point at the mantle-core boundary. The quantitative results appear to support this hypothesis; but the melting point at the centre of the earth is considerably lower than at the bottom of the mantle. According to these data, solidification from a molten state would commence at the core boundary and progress outward. A much greater amount of cooling through the mantle than hitherto expected by the proponents of the cooling-earth hypothesis would be required before the adiabatic temperature curve for the core could meet the melting-point curve for the core. If it is assumed that this cooling has occurred, then solidification would have recommenced

at the centre and progressed outward provided the melting-point gradient exceeded the adiabatic gradient. Jeffreys⁵ has shown that cooling by conduction alone could scarcely have progressed below the melting point in the mantle to depths greater than about 700 km. at the present age of the earth. It seems imperative, then, if the curves given above are reasonably close to the truth, to assume that cooling has been by slow convection currents in the 'solid' mantle. The alternative is that the melting point of iron must be considerably revised upwards and/or the melting point at the bottom of the mantle must be revised downwards.

As Simon has pointed out, the actual temperature at the boundary of the solid inner core would be the melting point of iron at that depth, since in the liquid part the actual temperature would be above the melting point while in the solid part it would be below the melting point. We might expect, then, that we could estimate the actual temperature in the liquid part of the core by computing the adiabatic gradient for this region and progressing outward from the 'known' temperature at the inner-core boundary. Valló's⁶ recent work, based on seismic data and theory of the solid state, gives $T_{\text{core}}/T_{\text{mantle}} = 1.38$, which leads to a mean gradient of 0.51° K./per km. in the liquid core. This is greater than the mean melting-point gradient of 0.33° K. per km. for this region as given by Simon's data. It would mean that no inner core could form from a cooling earth and still leave a liquid outer core, nor could convection currents occur as required by the Bullard-Elsasser theory of the origin of the earth's magnetic field. Bullard⁷ has estimated the mean adiabatic gradient in the liquid core to be 1.1° K. per km.; but his estimate was based on an assumed mean temperature of 10,000° K. Since the adiabatic temperature gradient is proportional to the temperature, Bullard's value reduces to 0.39° K. per km. if 3,500° K. is used instead of 10,000° K. This is still a little high, but could probably be reduced further by a more careful evaluation than was necessary for Bullard's calculations. With the data available at present, it is possible that convection currents would occur in the core as long as it is molten, and that the actual temperature lies close to Simon's melting curve.

The occurrence of a solid inner core may possibly be explained on the hypothesis of a cold origin for the earth with subsequent heating due to radioactivity. According to this hypothesis, the initial gradient would be essentially adiabatic with a temperature of about 2,000° K. at the mantle-core boundary⁸. Radioactive generation of heat, presumably concentrated near the earth's surface, would raise the temperatures so that the upper part of the mantle would melt⁹; the rising temperature in the interior would eventually meet the melting curve at the core boundary and melting would progress inward leaving a solid inner core. One would expect, however, that the actual temperature gradient in the liquid core would then be very small, if not reversed, so that convection currents could not arise. Furthermore, the layered nature of the earth would have to exist before melting began. This layering is more easily explained if the earth has passed through a molten stage.

The one conclusion we may draw with a fair degree of certainty and which depends on no particular theory of the earth's thermal history is that the actual temperature at the core boundary must lie

Fig. 1

between the upper limit given by the melting point at the bottom of the solid mantle, and the lower limit given by the melting point at the top of the liquid core, that is, between 5,000° K. and 3,000° K.

Fractionation of Isotopes by Distillation of some Organic Substances

In a recent communication having the above title, Baertschi, Kuhn and Kuhn¹ expressed surprise that substitution of carbon-13 for carbon-12 in the molecules CHCl_3 , CCl_4 , CH_3OH and C_2H_6 caused an enhancement of volatility, whereas substitution of chlorine-37 for chlorine-35 in the first two compounds, and of oxygen-18 for oxygen-16 in methanol, had the opposite effect. This led them to suggest that it might be a general rule for isotopic molecules containing a central atom that the molecular variety having the heavier isotope as central atom is more volatile than the isotopic molecule with the lighter central atom.

The purpose of this communication is to point out that these results can be understood on statistical thermodynamical grounds provided a plausible mechanism is assumed for intermolecular attraction in polyatomic molecules. It follows from the Saakur-Tetrode equation that the greater the mass of a molecule the greater is its translational entropy in the vapour, and therefore the greater is its probability of attaining the vapour state. (I wish to thank Prof. W. Kuhn and Dr. P. Baertschi for pointing out that the gas-mass-entropy effect will be compensated to some extent by the effect of mass on the entropy of the liquid.) A lucid explanation of this subtle connexion between volatility and molecular weight has been given by Sir Cyril Hinshelwood².

The entropy effect is, however, generally obscured by the over-riding influence of intermolecular attractions in the condensed phase, which normally increase with the size of the atom and with the number of atoms in the molecule. In consequence, greater molecular weight is usually associated with greater intermolecular attraction and lower volatility.

To explain the results of Kuhn *et al.*, it is necessary to postulate that intermolecular attraction is localized between nearest atoms of polyatomic molecules, and is not produced by the operation of central force fields between the molecules as units. In the case of carbon tetrachloride, it is clear that intermolecular attraction involving chlorine will predominate, since the carbon atoms are effectively screened. Thus isotopic replacement of carbon will mainly affect the entropy term, and the molecule containing the heavy isotope will be the more volatile. For isotopic replacement of chlorine, on the other hand, it appears

that the change in the entropy term is overruled by the change in the intermolecular attraction term and heavy chlorine lowers the volatility.

In the case of isotopically different polyatomic molecules, the relative vapour pressures P_H/P_L (where P_H and P_L are the vapour pressures of the heavy and light species respectively) can generally be expressed as a function of temperature as follows:

$$\log \frac{P_H}{P_L} = \Delta a - \frac{\Delta b}{RT}$$

Δa is usually positive because of the mass-entropy effect and favours the volatility of the heavier species. This tendency is opposed by Δb , which is positive and mainly reflects a difference ($\lambda_H - \lambda_L$) in the latent heat terms due to the heavier species having the smaller zero-point energy of quasi-oscillation in the liquid.

Assuming that the relative vapour pressures of isotopic carbon tetrachlorides conform to the above equation, and using $(\Delta a)_C$, $(\Delta b)_C$, $(\Delta a)_{Cl}$ and $(\Delta b)_{Cl}$ to represent the appropriate terms for carbon and chlorine exchange respectively, it follows from experimental data of Kuhn *et al.* that at 308° K. $(\Delta a)_C > (\Delta b)_C/RT$ and $(\Delta b)_{Cl}/RT > (\Delta a)_{Cl}$. Since chlorine exchange involves double the mass change of carbon exchange, it is probable that $(\Delta a)_{Cl} > (\Delta a)_C$ and $(\Delta b)_{Cl} > (\Delta b)_C$. Although this will lead to $(P_H/P_L)_C \neq (P_H/P_L)_{Cl}$, it should not appreciably alter the temperature $T = \Delta b/\Delta aR$ at which 'crossing-over' occurs. Below this temperature, the lighter species is more volatile, while above it the order of volatility is reversed. To explain the experimental results, it is further suggested that the ratio $(\Delta b)_{Cl}/(\Delta a)_{Cl}$ exceeds the ratio $(\Delta b)_C/(\Delta a)_C$ because of stereochemical factors which control the nature of intermolecular attraction.

This idea, which will be reported in full elsewhere, involves the assumption that the total intermolecular attraction per molecule in the liquid is the sum of the interactions involving pairs of atoms from neighbouring molecules, and that each type of atomic interaction (for example, $\text{C}\dots\text{C}$; $\text{C}\dots\text{Cl}$; $\text{Cl}\dots\text{Cl}$) has a separate zero-point energy of quasi-oscillation. On this basis, isotopic replacement involving the atomic interaction with the greatest zero-point energy will have the greatest influence on Δb . In general, the type of interaction having the greatest energy will also have the greatest zero-point energy, and in the above example will be $\text{Cl}\dots\text{Cl}$, followed in order by $\text{C}\dots\text{Cl}$ and $\text{C}\dots\text{C}$. Hence isotopic change of chlorine has a greater effect on Δb than a similar change in carbon. This postulate can thus give a qualitative explanation of the phenomena resulting from isotopic replacement in molecules containing shielded central atoms. Moreover, as a further consequence, it would predict a big change in Δb when any particularly strong intermolecular interaction is involved or when isotopes of small mass are exchanged, and it will be shown elsewhere that this is in accord with experimental observations. In fact, the results of Kuhn *et al.* on methanol provide an example of this behaviour. Thus, for carbon exchange the heavy species is more volatile, whereas in oxygen exchange the heavy species is less volatile. This comparison is complicated by the fact that oxygen exchange involves twice the change in mass for carbon exchange, but no such difficulty arises in comparing carbon exchange with hydrogen exchange. According to the above theory, CH_3OH should be more volatile than CH_3OD because of the great change in zero-point energy caused by hydrogen

exchange on the strong H...O interactions, and this is confirmed by the experimental results.

Mechanism of the Bursting of Bubbles

THE formation of drops, as the result of a gas or vapour bubble bursting at the surface of water, has been attributed to the break-up of the jet formed when liquid flows into the crater left by the burst bubble, and photographic evidence indicates that large drops are, in fact, formed in this way¹.

We have observed, however, that two separate mechanisms are involved in the bursting of a bubble—

Fig. 1

Fig. 2

one producing a cloud of droplets of diameter about 60 microns, and the other a few comparatively large drops of diameter about 1 mm. The various stages of the collapse are illustrated in Fig. 1, a-f. It will be observed that in the initial stage a protuberance develops on the hemispherical surface of the bubble, (b), the collapse of which produces the cloud of fine droplets and leaves a large gap in the bubble envelope (c). The escape of gas through this gap effectively disperses the cloud and imparts to the droplets a high velocity. Thereafter a crater is formed at the site of the bubble (d), and the incoming rush of liquid produces an unstable jet (e), which breaks up into one or more large drops (f).

Fig. 2 illustrates the way in which a thin film of liquid disintegrates to give the fine droplets observed in the initial stage of the burst.

A Long Spacing at about 30 kX. confirmed from a Fireclay

THE white clay from the Kurata Mine, Yamaguchi Prefecture, Japan, is largely composed of kaolinite; in flinty massive specimens it is commonly well crystallized, whereas in powdery massive specimens it is disordered. The clear resolution of the (111), (111) doublet is revealed in X-ray powder reflexions of a certain flinty specimen. The disordered behaviour is marked by a band of the two-dimensional type associated with (020). These facts were first reported by G. W. Brindley and K. Robinson for specimens from England. It is noteworthy in the present case that reflexions from the latter type are frequently accompanied by those of montmorillonite as well as a clear powder reflexion at $29.8 (\pm 0.5)$ kX. The basal reflexions of the montmorillonite are

14.7 (± 0.2) kX. (001), 4.93 kX. (003) and 2.97 kX. (005), and of the kaolinite, 7.13, kX. (001), 3.58 kX. (002) and 2.40 kX. (003). The intensity of the 14.7 line is commonly proportional to that of the 29.8 kX. line; but the ratio of the intensity of the kaolinite line to that of montmorillonite varies from specimen to specimen. The (060) spacing is 1.491, kX., which suggests that the amount of aluminium replacing silicon is small.

The reference specimens were ignited at temperatures of 300°, 500°, 700°, 900° and 1,100° C. for one hour and cooled and studied by X-rays immediately after cooling. The X-ray powder pattern was not affected by heating at 300° C. At 500° C., kaolinite lines as well as the 29.8 kX. line had disappeared; montmorillonite lines remained weak and unchanged except the 14.7 kX. line, which was replaced by a line at 11.7 (± 0.2) kX. The powder pattern at 700° C. agrees perfectly with that obtained at 500° C., that is, the 11.7 kX. line is persistent even at 700° C. At 900° C. most of the powder lines are just visible; mullite lines are revealed in the pattern obtained by heating at 1,100° C. Thus the usual 9.6 kX. line of dehydrated montmorillonite never appeared in the temperature range investigated.

Treatment with ethylene glycol caused the 14.7 kX. line to be replaced by a 15.6 (± 0.3) kX. line, and the 29.8 kX. line by a 32.3 (± 0.5) kX. line. Treatment with water expanded the 14.7 kX. spacing to 16 kX., and the 29.8 kX. spacing to 32-33 kX.

A specimen ignited at 700° C. was cooled and sealed in a glass tube immediately. At the beginning of the X-ray experiment, the specimen was transferred from the glass tube to a shallow cell on the slide glass containing phosphorus pentoxide to prevent adsorption of moisture into the specimen during X-radiation. Even with this treatment the 11.7 kX. line is still persistent at 700° C. To prevent the effect of exchangeable cations, the clay was electrolysed and studied by X-rays at room temperature. The X-ray powder pattern thus obtained agrees perfectly with that of the original specimen.

To account for these unusual X-ray properties, three types of lattices can be considered: (1) kaolinite; (2) the usual montmorillonite lattice with two sheets of water molecules (*M*-lattice), with a cell height of 15.4 kX., which is expected to decrease to 9.6 kX. by heating at least at 300° C., and to expand to 17.0 kX. with ethylene glycol treatment; (3) an unusual lattice (*G*-lattice) showing a configuration represented by a gibbsite layer interleaved between two adjacent silicate layers (pyrophyllite units); its cell height approximates to 14.0 kX., which is expected to be unaffected by the treatments with ethylene glycol and water, and may be persistent at least up to 700° C.

Thus it is considered that the 14.7 kX. line is caused by a mixed-layer structure containing the *M*-lattice and the *G*-lattice; this line is expected to expand to 15.6 kX., when the *M*-lattice expands to 17.0 kX. by treatment with ethylene glycol, and to decrease to 11.7 kX. when the *M*-lattice contracts to 9.6 kX. by dehydration. The long spacing

of 29.8 kX. is considered to be caused by a super-lattice composed of these two lattices. It may be expected that the super-lattice will be completely destroyed at the same time as the *M*-lattice becomes dehydrated.

We are indebted to Prof. G. W. Brindley for discussion of this problem.

Effect of Previous Stress-Strain History on the Dynamic Hysteresis Loop for Rubber in Compression

SEVERAL investigators have shown that the behaviour of rubber is affected appreciably by its previous stress-strain history. Their observations, in the main however, are based on indirect measurements of modulus and damping characteristics. Few, if any, have recorded stress-strain relationships in these investigations. Although it might be possible to calculate, from these indirect measurements, the slope and area of the dynamic hysteresis loop; such measurements give no indication of the position of the hysteresis loop relative to the axes of stress and strain. The position of the loop is of fundamental importance in assessing the dynamic characteristics of rubber, and plays a big part, for example, in determining the resilience of the material. To the best of our knowledge, little, or nothing, is known of the effect of previous stress-strain history on the position of the dynamic hysteresis loop, and it is felt that the test record presented below may be of immediate interest to workers in this field. The record forms part of a major investigation which it is hoped to publish later.

The test recorded in Fig. 1 consisted of several hysteresis loops carried out at constant frequency, each about a different mean deformation. The mean

Fig. 1. Effect of previous history. Small loops at 100 c./m.; dotted loop at 1 c./15 min.

deformation was increased in increments up to a predetermined maximum, and then reduced to zero. It will be seen that the loops recorded on the 'return path' do not coincide with those on the 'outward path'. This difference persisted even when an interval of up to 30 min. was allowed after each adjustment of the mean deformation before recording the loop in question. The small hysteresis loops lie on the periphery of a larger loop which was recorded over the same range of deformation. This larger loop was performed very slowly—the rate being 1 cycle in 15 min. It would appear from these results that the so-called 'history effect' is but another manifestation of hysteresis.

Fig. 2

The test was repeated with dynamic loops of larger amplitude from which measurements could be made of area and slope. No difference could be detected in either the areas or slopes of loops recorded at corresponding mean deformations over much of the outward and return paths.

The results presented here have a bearing on some previous observations concerning the terms resilience and percentage damping¹. The term percentage damping—defined as the ratio of the loop area $ABCD$ (Fig. 2) to the area $ABCE$ —does not permit quantitative measurements to be made of the movement of the loop, since the line AE is not a fixed reference line but moves with the loop. The term resilience, on the other hand—defined for the upper loop as the ratio of area $NADCM$ to $NABCM$ —will theoretically permit a quantitative assessment to be made of the shift of the loop. In practice, however, since the areas involved are comparatively large and almost equal, the term resilience does not bring out the difference between the upper and lower loops. Therefore, before any quantitative work can be attempted on the effect of stress-strain history, the definition of some suitable means of measuring the effect must be agreed upon.

Regularities in the F_2 -Region of the Ionosphere

THE variation of the maximum ionization density ($N_{\max} F_2$) of the F_2 -region of the ionosphere is known generally to depart widely from the $\sqrt{\cos \chi}$ law of Chapman (where χ is the zenith distance of the sun). It has, however, been recently shown by Ratcliffe¹ that if, instead of $N_{\max} F_2$, the total ion content (per unit cross-section) of the F_2 -region ($n_T F_2$) be considered, the variations of the total ion content with $\sqrt{\cos \chi}$ appear to be more regular. I have followed up this view², and have shown that if, in place of

$n_T F_2$, the total ion content of the F_1 - and F_2 -region as a whole (n_T) is considered, then the variations of n_T with $\sqrt{\cos \chi}$ become very much more regular. However, it was observed that on these otherwise regular variation curves (diurnal and seasonal) certain abnormal peaks are superposed. I had provisionally explained these as due to the effects of solar tides, superposing themselves on the variations due to changes in the zenithal position of the sun. In order to check this assumption seasonal variation curves of the monthly mean values of the 24-hr. average total ion content (n_T) were plotted (Figs. 1 a, b, c). These seasonal variation curves—from which the solar tidal effects are obviously eliminated—are found to closely follow the corresponding $\cos \chi$ curves, justifying the assumptions made. The data analysed were for the same three stations—Slough, Falkland Islands and Singapore—as had been studied in the earlier work.

These results also support the recent hypothesis³ that the F_1 - and F_2 -regions are formed by a common ionizing process (ionization of oxygen at its first ionization potential), and that in the single bank of ionization so formed there is produced, besides the

Fig. 1. Seasonal variation curves of the monthly mean values of n_T and $\cos \chi$ in 1951 (χ is the noon-time zenith angle of the sun)

Fig. 2. Variation with latitude of the monthly mean noon values of $f°F_1$ and n_+ for April 1953

usual Chapman maximum F_1 , a secondary maximum F_2 higher up, due to the peculiar physical characteristics of the region above F_1 -maximum.

An interesting fact regarding the latitudinal variation of the monthly mean values of noon-time total ion content was also noticed. The curve in Fig. 2 shows that, unlike the curve depicting the latitudinal variation of noon-time $f°F_1$ (dotted), that of the total ion content does not show the 'Appleton dip' around the geomagnetic equator. However, the maximum occurs on the geomagnetic equator rather than on the geographic equator, showing that the distribution of even the total ion content of the F_1 - and F_2 -regions is subject to geomagnetic control.

My thanks are due to Prof. S. K. Mitra for his guidance and interest in the work. Thanks are also due to the Scientific Man-Power Committee, Government of India, for financial help.

Thermal Diffusion Potentials and the Soret Effect

WHEN a temperature gradient is applied to a homogeneous solution of an electrolyte, there is a tendency for a concentration gradient to be established (Soret effect). The thermal diffusion potential associated with the temperature gradient should change during the establishment of the Soret equilibrium. For a cell of the type:

the change in e.m.f. during the establishment of this equilibrium can be calculated theoretically¹⁻³. In the simplest case³, where the solution contains a uni-univalent salt obeying the ideal law, the change in e.m.f., $\Delta\epsilon$, for a cell containing electrodes reversible to anions is

$$\Delta\epsilon = -2RT/F \cdot n_+ d/dT (\ln m); \quad (1)$$

and, for one with cation-reversible electrodes,

$$\Delta\epsilon = +2RT/F \cdot n_- d/dT (\ln m); \quad (2)$$

where an increase in concentration at the hot electrode is taken as positive, and n_+ and n_- represent the transference numbers of the cation and anion respectively.

Conditions suitable for the establishment of the Soret effect are not easily attained, and earlier experiments³ designed to provide a test of the above equations were only partially successful. The difficulty of verifying these equations, though not of determining Soret coefficients, may be overcome by a modification of the technique used in this laboratory for the measurement of thermoelectric e.m.f. values at the time of the establishment of the thermal gradient³. Using cells of substantially the same design as those used previously, we have measured the e.m.f. ($\Delta\epsilon$) of the cell:

and compared it with that found for an identical system with a solution of molality m in contact with both electrodes. The results obtained in the two cases so far examined are shown in Table 1.

The mean temperature in these experiments was approximately 29°C. The values of $d\epsilon/dT$ for a cell with no concentration gradient were obtained by interpolation from the results of independent experiments⁴.

The experimental values have the sign predicted by equation (2) and, in the second case, the numerical agreement is excellent. In the first, the discrepancy between the observed and the calculated value is considerably greater than the experimental error in the e.m.f. measurements, and the experimental value requires confirmation.

Clearly, this method permits the investigation of deviations from the ideal equations shown above, and suggests a new method of investigating the Soret effect. An empirical knowledge of the relation $\Delta\epsilon$ and $d\epsilon/dT (\ln m)$ would enable Soret coefficients to be calculated from measurements of $\Delta\epsilon$ in cells in which the Soret equilibrium is established between plane parallel electrodes the surface temperature of which is known accurately. This method is not limited to the rather high concentrations employed in earlier work in this field³, and measurements in

Anhydrous Hydrogen Fluoride as a Solvent for Proteins

ANHYDROUS hydrogen fluoride (m.p., $-83^{\circ}\text{C}.$; b.p., $19.5^{\circ}\text{C}.$) has been found to be a powerful solvent for a wide variety of proteins. Experiments were carried out in transparent tubes moulded or machined from polychlorotrifluoroethylene polymer; these tubes containing the intensively dried protein samples could be attached to a metal vacuum system, hydrogen fluoride added by distillation, and direct visual observations made in the absence of moisture. Among proteins which are readily soluble in hydrogen fluoride at 0° are ribonuclease, lysozyme, pepsin, trypsin, crystallized egg albumin, bovine plasma albumin, bovine plasma globulin, edestin, peanut protein globulin, casein, zein, silk fibroin, hide collagen, insulin and adrenocorticotrophic hormone. These are all soluble at least to the extent of 20 mgm. per ml., and much more concentrated solutions can in general easily be prepared. Thus, a solution containing 350 mgm. per ml. bovine plasma albumin is still quite fluid at $0^{\circ}\text{C}.$ The solutions are clear, colourless to faint amber, and are very much less viscous than corresponding aqueous solutions. The globular proteins dissolve rapidly even at $-78^{\circ}\text{C}.$, whereas silk fibroin and hide collagen undergo strong swelling and require many hours at room temperature for complete solution.

The iron-containing proteins cytochrome c, catalase and haemoglobin are very soluble in hydrogen fluoride. They give pink solutions which have absorption spectra very similar to those exhibited in water. The ability of metal-complex compounds to exist in hydrogen fluoride appears to be a general phenomenon, for it is found that metal phthalocyanines, cobalt(III)amine-complex compounds, and a considerable variety of other metal-complex compounds dissolve in hydrogen fluoride without precipitation of metal fluoride.

Proteins were recovered by evaporation of the solutions on the vacuum line. Films of recovered silk fibroin and collagen gave characteristic polypeptide infra-red spectra. Of the proteins mentioned above, ribonuclease, lysozyme, trypsin, cytochrome c, haemoglobin, hide collagen, insulin and adrenocorticotrophic hormone are recovered in a water-soluble state after remaining in hydrogen fluoride solution for 2 hr. at $0^{\circ}\text{C}.$ Recovered insulin was found by bioassay on mice to have retained 80 per cent of its initial activity, and similarly adrenocorticotrophic hormone was recovered intact with full retention of its original biological activity. The biological properties of the other water-soluble proteins after recovery remain to be examined. The surprising retention of biological activity by insulin

and adrenocorticotrophic hormone after dissolution and recovery from hydrogen fluoride solution suggests that this solvent may have real significance in protein studies.

Because of its low freezing point, liquid hydrogen fluoride may be an interesting medium for carrying out chemical reactions on proteins at very low temperatures. For example, it has been observed that ozone, which appears to be quite soluble in hydrogen fluoride, changes a pink haemoglobin solution to green. Hydrogen peroxide solutions in hydrogen fluoride (prepared by addition of the 1:1 urea-hydrogen peroxide addition compound) change the pink colour of cytochrome c and catalase solutions to yellow. Trioxane, which has been found to be highly soluble in hydrogen fluoride, gives a typical formaldehyde reaction when added to a protein dissolved in hydrogen fluoride; the viscosity of the solution increases until a rigid gel results. These and other characteristic protein reactions with many of the usual protein reagents can thus be carried out at much lower temperatures than has been possible in aqueous systems.

Details of these experiments will appear elsewhere.

Formation of a Mixed Disulphide of Cysteine and Glutathione

In our studies on the synthesis of glutathione by *Saccharomyces cerevisiae*, the yeast was incubated in 0.01 M potassium dihydrogen phosphate with cysteine containing sulphur-35. Samples of the mixture were removed at intervals and the component amino-acids and peptides were separated by paper chromatography. The chromatograms were sprayed with a ninhydrin solution and autoradiograms of the chromatograms were made on Kodak No-screen X-ray film.

When a phenol-water mixture was used for preparing a descending chromatogram, a spot which contained a considerable amount of sulphur-35 was observed. This substance ($R_F = 0.27$) was intermediate between glutathione disulphide ($R_F = 0.16$) and cystine ($R_F = 0.42$). It was found in largest amounts in the mixture of yeast and sulphur-35 cysteine immediately after the cysteine had been added to the yeast and before it had been metabolized by the cells to any extent. Since both cysteine and glutathione are oxidized to the disulphides during chromatography under our conditions, it seemed possible that the new substance was a mixed disulphide of cysteine and glutathione formed not by the yeast but by oxidation by the air. The intermediate compound was shown, indeed, to be a disulphide by the use of Toennies's reagent¹.

Further evidence supporting the view that this compound was a mixed disulphide of cysteine and glutathione and that it was formed in the absence of yeast cells was obtained by mixing cysteine and glutathione in aqueous solution in the absence of yeast cells and also by using cysteine or glutathione labelled with radioactive sulphur. A solution of sulphur-35 cysteine was mixed with non-labelled glutathione in the absence of yeast cells, and this mixture was chromatographed immediately after being prepared.

Again three substances which reacted with ninhydrin and which had the R_f values mentioned above were found. Cystine and the intermediate spot were shown by an autoradiograph of the paper chromatogram to contain sulphur-35, while the glutathione disulphide spot did not. By counting the filter paper chromatogram with a thin end-window Geiger-Müller tube, it was found that 30 per cent of the sulphur-35 cysteine was incorporated into the intermediate compound when the initial solution contained equimolar amounts of sulphur-35 cysteine and glutathione.

A similar experiment was carried out with glutathione containing sulphur-35 and non-labelled cysteine. When the sulphur-35 glutathione and cysteine were mixed in solution and the mixture chromatographed, the intermediate disulphide spot again appeared. This substance and glutathione disulphide were shown to be radioactive whereas the cysteine spot was not. It was concluded, therefore, that this material was most probably a mixed disulphide of cysteine and glutathione:

Wikberg² has reported the formation of a mixed disulphide of glutathione and cysteinylglycine when glutathione was partially hydrolysed. His mixed disulphide was separated by paper electrophoresis from cystine and glutathione disulphide. He also reported the preparation of a mixed disulphide of cysteine and glutathione by oxidation with perhydrol at pH 7.5.

The results reported here were discussed before the American Chemical Society Meeting at Los Angeles in March 1953.

A Method for the Cleavage of 2,4-Dinitrophenylhydrazones and Its Application to Steroidal Ketones

2,4-DINITROPHENYLHYDRAZONES have proved very useful derivatives for identification purposes, but have so far found only limited application in preparative work. This is due to the fact that there exists no general method for the regeneration of the corresponding carbonyl compounds. As Djerassi pointed out¹, the failure to cleave 2,4-dinitrophenylhydrazones has imposed considerable limitations on the use of the Mattox-Kendall² dehydrobromination method in the field of steroid chemistry. Thus, in the case of 2,4-dinitrophenylhydrazones of $\Delta^{1,4}$ -dien-3-ketosteroids, only about 5-10 per cent of ketone could be recovered after treatment with pyruvic acid and hydrobromic acid, and derivatives of $\Delta^{1,4}$ -dien-3-ketosteroids could not be split at all¹.

We have now found that the splitting of these 2,4-dinitrophenylhydrazones can be achieved in good yields by the following general procedure, the quantities and times required for saturated-, Δ^1 , and Δ^4 -3-ketosteroids being denoted by (a), and those for $\Delta^{1,4}$ and $\Delta^{4,6}$ -3-ketosteroids by (b). The 2,4-dinitrophenylhydrazone (1 gm.) is dissolved in acetone

(a, 200 c.c.; b, 500 c.c.) containing concentrated hydrochloric acid (a, 5 c.c.; b, 10-20 c.c.) and the solution is refluxed (a, 45 min.; b, 7-8 hr.); this displacement can also be brought about at ordinary temperature for 2,4-dinitrophenylhydrazones of class (a) (24 hr.) and for the more soluble derivatives of class (b) (15 days). The yellow to orange-yellow solution is slightly cooled and treated with stannous chloride (5 gm.) dissolved in concentrated hydrochloric acid (20 c.c.). Water (a, 30 c.c.; b, 80 c.c.) is added and the mixture heated to reflux in an atmosphere of nitrogen for 45 min.; further heating decreases the yield and purity of the ketone recovered. With 2,4-dinitrophenylhydrazones of both classes, this reduction can be carried out at ordinary temperature (24 hr.). The acetone is distilled off under reduced pressure at room temperature, the residue extracted with benzene, and the organic layer washed with 1 N hydrochloric acid until no more coloured material is removed. The benzene solution is finally washed with water and evaporated. The recovered ketone is purified by the usual methods.

Using this procedure the following results were obtained with approximately 1 gm. each of 2,4-dinitrophenylhydrazones:

- (1) Δ^1 -cholestan-3-one: yield, 98 per cent (m.p., 127-128°; lit., 129-130°).
- (2) Δ^4 -cholestan-3-one: yield, 96 per cent (m.p., 78-79.5°; lit., 80-8°).
- (3) Δ^1 -cholestan-3-one: yield, 84 per cent (m.p., 99-100° (from dil. alcohol); lit., 98-100°).
- (4) Testosterone: yield, 98 per cent (m.p., 143-150°; lit., 153°).
- (5) Progesterone (via 2,4-dinitrophenylhydrazone): yield, 86 per cent (m.p., 120° (from pet. eth.); lit., 121°).
- (6) $\Delta^{1,4}$ -cholestan-3-one: yield, 83 per cent (m.p., 110-111°; lit., 113°).
- (7) $\Delta^{4,6}$ -cholestan-3-one: yield, 88 per cent.
- (8) Methyl $\Delta^{1,4}$ -3-ketostrioladienate: yield, 67 per cent (m.p., 153-155°; lit., 156°).

As it is somewhat difficult to purify $\Delta^{4,6}$ -cholestan-3-one on a small scale, the yield was determined by reconstituting it into the corresponding 2,4-dinitrophenylhydrazone (m.p. 234° from acetic acid).

The successful cleavage of the $\Delta^{1,4}$ -dien-3-one derivatives supports Djerassi's assumption that they are true hydrazones and not pyrazoline derivatives (cf. ref. 1, footnote 19, p. 1005).

The final benzene solution of methyl $\Delta^{1,4}$ -3-ketostrioladienate was extracted with sodium bicarbonate solution. On acidification this gave 110 mgm. of an acid (m.p. 277-280° with dec.), showing that partial hydrolysis of the ester group had occurred.

Other ketones, such as dibenzyl acetone, have also been recovered successfully by this treatment.

We suggest that the method is of wider application and that it may be useful in other fields of preparative organic chemistry.

We wish to express our thanks to Dr. Carl Djerassi, to the CIBA, S.A. (Basle) and to the Schering A.G. (Berlin) for gifts of specimens which have greatly facilitated this work. Full details of this investigation, including improvements in the preparation and purification of some 2,4-dinitrophenylhydrazones of 3-ketosteroids, will be published in the *Bull. Soc. Chim. Belg.*

Formation of Acetyl Phosphate by the Action of X-Rays on Monoethyl Phosphoric Acid in Aqueous Solution

Our earlier work on the chemical action of X-rays on the nucleic acids in aqueous systems¹ has led us to suggest that labile compounds, including labile phosphate esters, are formed on irradiation, and that these may play some part in the breakdown of the polynucleotides. Following some observations on the effects of the radiation on relatively simple phosphate esters (for example, glycerophosphates, phosphoglyceric acid), we have suggested that, in general, oxidative attack at a $> \text{CH}(\text{OH})$ (secondary alcohol) group by the free radicals can lead to the formation of a $> \text{C}=\text{O}$ (carbonyl) group, and that, if the latter is α - or β - to a phosphate group, a more or less labile ester is produced².

In order to elucidate further the chemical mechanism by which labile phosphate esters are formed in these circumstances, a systematic investigation of the effects of X-rays on a number of phosphate esters has been undertaken.

We are now reporting some observations on one of the simplest phosphate esters, namely, monoethyl phosphoric acid. Here one might expect that oxidative attack by the radicals on the primary phosphoryl group ($-\text{CH}_2\text{OPO}(\text{OH})_2$) would lead, by a relatively straightforward process, to the corresponding aldehyde, together with inorganic phosphate. On the other hand, we may apply, in the presence of oxygen, a mechanism which we have recently found to be operative in the attack on certain simple aliphatic compounds³; this involves reaction of the organic radical primarily formed with molecular oxygen, which can lead to an organic hydroperoxide.

In the case of monoethyl phosphoric acid, the hydroperoxide resulting from attack on the primary phosphoryl group would have structure (I), subsequent decomposition of which could lead to acetyl phosphate (II):

We have now demonstrated that this latter mechanism does, in fact, also hold for this system, since we have been able to show that irradiation of monoethyl phosphoric acid with X-rays in the presence of oxygen gives acetyl phosphate, among other products. This conclusion is based on the following experimental evidence.

(i) Slow liberation of inorganic phosphate after irradiation.

(ii) A positive Lipmann reaction⁴ for acetyl phosphate, namely, formation of the corresponding hydroxamic acid which gave the characteristic ferric salt in acid solution (ferric acetylhydroxamate was identified by its absorption spectrum).

(iii) A difference in the yields of inorganic phosphate as determined separately by the methods of Lowry and Lopez⁵ and Berenblum and Chain⁶; whereas the former is suitable for the determination of inorganic phosphate in the presence of acetyl phosphate⁷, under the conditions of the Berenblum-Chain procedure, it is known that acetyl phosphate is rapidly hydrolysed⁸.

A typical experiment was as follows: 100 ml. of a solution of monoethyl phosphoric acid (0.1 per cent calcium salt), adjusted to pH 5.5 and saturated with

oxygen (1 atm.), were irradiated with X-rays (200 kV.) with a total dose of 7×10^4 r. (integral dose-rate = 2,840 r./min.). Under these conditions, 15 μ moles of acetyl phosphate per 100 ml. were produced. At the same time, some acetaldehyde was formed and about 5 μ moles of inorganic phosphate; somewhat more inorganic phosphate than acetaldehyde is to be expected, owing to the slight decomposition of the acetyl phosphate during irradiation.

These results show that one of the major processes occurring under these conditions is that leading to acetyl phosphate. In agreement with the mechanism outlined above, we have found that the formation of acetyl phosphate requires the presence of molecular oxygen.

These observations would suggest that certain other compounds containing the primary phosphoryl group ($-\text{CH}_2\text{OPO}(\text{OH})_2$) may give, on irradiation in the presence of oxygen, the corresponding acyl phosphate to a smaller or greater extent.

Thus, labilization of organic phosphate esters can be due to the production of carbonyl groups (α - or β - to the phosphate) and/or, under certain conditions, to the formation of acyl phosphates. Carbonyl groups can be produced by OH radicals (generated by the action of the ionizing radiation on water, namely, $\text{H}_2\text{O} \rightsquigarrow \text{H} + \text{OH}$), and their formation is therefore not dependent upon the presence of oxygen in solution, although, for reasons discussed previously^{3,4}, oxygen should, in general, enhance the yield of the carbonyl compound. On the other hand, for the formation of the acyl phosphate, as described above, the presence of molecular oxygen is essential.

This appears to be the first instance in which acetyl phosphate is formed by a relatively simple oxidation process in aqueous solution.

Our thanks are due to the Northern Council of the British Empire Cancer Campaign and to the Rockefeller Foundation for financial support.

A Trough for Paper Chromatography consisting of Segments

The sensitivity of paper chromatography is such that lack of reproducibility often hampers the systematic approach. In order to facilitate measurements under identical conditions, we are using a glass trough which consists of four equal segments.

Each segment can hold duplicate strips of paper of 7 cm. $\times$ 40 cm., or one can apply two sheets of paper of 40 cm. $\times$ 40 cm. if three small cuts are made on the top edge (see Fig. 1). To mark the movement of liquid flowing from one segment, 1 c.c. of

Fig. 1. Apparatus for descending paper chromatography with a trough consisting of four segments

10⁻³ M quinine sulphate is added to segments 1 and 3; after the paper has been dried, fluorescence shows clearly the borders of the solvents flowing from each segment. If the position of the trough is exactly horizontal, these borders are found to be perfectly vertical to the axis of the trough. We can thus establish a pH gradient on a paper, when each segment contains a buffered solvent system of a slightly different pH. When this technique is applied to protein hydrolysates as a second run (first run with propanol/water 7:3), it is possible to accelerate or to slow down the movement of amino-acids with polar groups; in many instances incomplete separation can be overcome.

The following example demonstrates the effect of a variation of the ionic strength of the buffer system on the separation of arginine, lysine and glutamic acid. The solvent system *m*-cresol/phenol 1:1 was used as described by Levy and Chung¹; 0.1 M potassium dihydrogen phosphate/0.05 M sodium borate of pH 9.0 and of varying ionic strength was added as buffer. The run lasted for 17 hr. at 18° on Whatman No. 1 paper. One paper of 40 cm. × 40 cm. was used, and at the end it was cut into four equal strips for photography. The colour was developed with ninhydrin according to the method of Moore and Stein².

Besides the *R_F*-values, we give in Table 1 the planimeter value of the areas of the spots. We are using the latter as a measure of the compactness of spots; but we do not consider them to allow a quantitative evaluation of single amino-acids as has been suggested elsewhere.

Fig. 2. One-dimensional chromatograms showing the influence of an increase of the ionic strength of the borate buffer on the same paper under identical conditions

Table 1

μ	Ionic strength of borate buffer							
	0.0000		0.0067		0.0114		0.0170	
	<i>R_F</i>	PI*	<i>R_F</i>	PI*	<i>R_F</i>	PI*	<i>R_F</i>	PI*
Arginine	0.37		0.33	1.00	0.34	0.41	0.37	0.30
Lysine			0.21	0.17	0.28	0.15	0.30	0.13
Glutamic acid	not sep.		0.14	0.53	0.13	0.46	0.10	0.37

* Planimeter reading.

Thus an increasing ionic strength of the borate buffer leads to an improved separation of basic and acidic amino-acids, as well as to more compact spots.

Bicarbonate Content of the Blastocyst Fluid and Carbonic Anhydrase in the Pregnant Rabbit Uterus

It has been noted in the course of a chemical investigation of the properties of rabbit blastocysts that the fluid which fills the cavity of the blastocyst at six and seven days after mating turns distinctly alkaline after withdrawal and standing in air for a few moments, whereas at eight days, in similar circumstances, the reaction of the fluid remains practically unaltered, at pH 7.8¹. In view of the low buffering capacity of the fluid obtained from six- and seven-day old blastocysts, it was thought likely that bicarbonate may be responsible for the shift in the pH value. Accordingly, manometric determinations were carried out in samples of fluid from blastocysts at six, seven and eight days after mating, collected by means of a technique described elsewhere¹.

The results of the manometric experiments have justified our assumption: a remarkably high content of bicarbonate, three times that present in maternal serum, was found in the unimplanted six-day old blastocysts; at seven days, when the majority of the blastocysts are in the process of incipient implantation, it was less, but there was still a considerable amount of bicarbonate in the fluid; on the other hand, at eight days, when implantation is complete, the level of bicarbonate was somewhat below that recorded for maternal blood (Fig. 1). As a matter of interest, it may be added here that we have also examined the bicarbonate content in cow ovarian follicle fluid from early luteal phases², and in cow and pig allantoic and amniotic fluids (at twenty-nine and twenty days of pregnancy, respectively); except for the pig allantoic fluid, which at that stage appeared to lack bicarbonate, the other fluids exhibited bicarbonate values close to those found in blood plasma.

The occurrence of bicarbonate in a high concentration in the early blastocysts has led us to investigate the presence of carbonic anhydrase in the uterus. The uterine mucosa was collected from thoroughly bled six- and seven-day pregnant does, and also from non-pregnant rabbits, and assays of carbonic anhydrase activity were carried out in saline-phosphate extracts from the mucosa, by means of the colorimetric³ and boat⁴ methods. It was found that the

Fig. 1. Bicarbonate content in the rabbit blastocyst fluid: O, blastocyst fluid; X, maternal serum

non-pregnant uterine mucosa possessed practically no carbonic anhydrase activity; the extracts made from the mucosa of the pregnant uteri, however, invariably showed strong carbonic anhydrase activity which could be completely inhibited by low concentrations of sulphanilamide, the specific inhibitor of this enzyme⁶; the residual blood in the uterine extracts accounted for not more than a tenth to a twentieth of the total enzymic activity inherent in the mucous membrane.

It is too early to speculate on the mechanism of bicarbonate formation in the early blastocysts, and on the role of carbonic anhydrase in the pregnant uterus. However, by way of commentary, we should like to recall briefly certain facts which may well have some bearing upon our observations. Concerning first the presence of bicarbonate in the rapidly growing blastocysts, it is significant that the requirement for bicarbonate, and also for phosphate ions, in synthetic media for embryonic cells proliferating in tissue cultures has repeatedly been stressed of late^{6,7}. While, however, the inner cell mass of the rabbit blastocysts obviously has at its disposal an ample supply of bicarbonate, the total phosphorus content of whole six-day-old blastocysts was found to be not more than 2.5–2.8 mgm. per cent. Next, with reference to the occurrence of carbonic anhydrase in the female reproductive tract, it is noteworthy that some time ago its presence was reported⁸ in the uterine epithelium of egg-laying hens. Lastly, certain observations of Meldrum and Roughton⁹ may also be relevant to our findings; these authors have observed that early foetal goat blood contained but traces of carbonic anhydrase, and that even towards the end of gestation foetal blood still possessed only 10 per cent of the activity of maternal blood; furthermore, a similar deficiency in carbonic anhydrase is known to exist in chicken embryos¹⁰.

Efforts are being made to extend to other species the present study on the distribution of uterine carbonic anhydrase throughout the entire period of pregnancy, in an endeavour to establish the physiological significance of this enzyme for the developing embryo; it is hoped that at the same time a clue

may be found to account for the high content of bicarbonate in the early blastocysts.

Ruminant-like Digestion in a Marsupial

WITH very few exceptions, animals do not produce an alimentary cellulase; consequently cellulose, which may constitute a considerable proportion of the diet of herbivores under many environmental conditions, is made available as a nutrient only by the fermentative activities of the microbial population of the alimentary tract. In most mammals this occurs in the oecum and colon, where the material is delayed long enough for effective fermentation. Their digestive physiology is nevertheless characterized by the absorption of glucose. This is the main metabolic fuel and is found in high concentration in the blood, a much reduced level resulting in coma.

The contrasting digestive physiology of ruminants has been extensively investigated in recent years. Ingested food passes directly to the rumen where a considerable quantity of the cellulose, as well as the other more soluble carbohydrates, undergoes fermentation resulting in a mixture of fatty acids¹ along with carbon dioxide and methane. Favourable growth conditions for the rumen microbial population are maintained by the copious alkaline salivary secretion. This pregastric fermentation means that little or no glucose-yielding materials are presented for absorption from the intestines. This is reflected in a much lower blood-glucose level in ruminants (35.5 mgm. per cent)² than in non-ruminants (80 mgm. per cent). Of the volatile fatty acids absorbed from the rumen and large intestines³, part are gluconeogenic, as most of the circulating acid is acetic acid, which has a glucose-sparing action in the tissues⁴. Consistent with this, very low blood-glucose levels after insulin treatment are well tolerated⁵.

The experiments on the macropod marsupial (*Sotorius brachyurus*) reported briefly here were initiated as a result of three unrelated observations: (a) dissections showed that the stomach was comparatively large, sacculated in the upper regions and possessed a well-defined oesophageal groove; (b) unconfirmed reports of cud-chewing in kangaroos; and (c) the finding, in connexion with studies of adrenal functions⁶, that the normal low blood-sugar could be lowered still further by insulin treatment without overt deleterious effect.

A ruminant-like digestion was thus suggested, and microscopical observation on stomach contents con-

firmed the presence of a rich microbial population similar to, but rather simpler than, that of the sheep. No ciliates have been observed; but this may be due to the diet. The digestibility of the cellulose has not been assessed, but extensive microbial erosion of this material within the stomach has been observed. The steam-volatile acids produced in the upper stomach are almost completely absorbed by the time the ingesta reaches the fundus. The pH of the upper stomach varies between 4.6, and 8.0, according to the activities of the micro-organisms and the level of fatty acids (range 15–2 M/mol. per cent). The identity of the volatile acids has not been investigated, nor the source of alkali to the upper stomach.

Blood drawn from the aorta, the vena cava, hepatic-portal vein and the hepatic vein confirm the relatively low blood-sugar status of the animal, and show clearly that the fatty acids produced in the stomach and caecum are absorbed into the portal vein. Some of these acids are removed in the liver, and comparison of arterial values and venous returns demonstrate clearly that fatty acid is removed by the tissues. These experiments will be reported fully elsewhere.

These findings are of interest on two counts. (1) It is generally held that the evolutionary lines emerging from therapsid reptiles and leading to marsupials and eutheria have been separate since the Cretaceous. This means that the ruminant type of digestion has been developed independently in marsupial macropods and eutherian ruminants. It is therefore a new and compelling example of parallel (or convergent) evolution. (2) *Setonix*, domesticated and averaging only 2–3 kgm., promises to be a cheap and fruitful tool for metabolic studies parallel to those on domestic ruminants.

The marsupial-holding pens were erected with funds from the Commonwealth Research Grants to the University; salary and expenses for G. Sharman were from a Nuffield grant.

Intravital Staining in Titrations of Group B Coxsackie Viruses in Weaned Mice

GROUP B Coxsackie viruses have been shown to be capable of producing a severe pancreatitis in weanling and adult mice¹. Necrosis of pancreatic acinar tissue occurs within a few days of infection and involves a high proportion of the cells in affected areas. These observations, together with the affinity of necrotic tissue for acid intravital dyes, have been utilized in the development of a technique for the rapid titration of pancreatotropic group B strains in weaned mice. Briefly, the technique is as follows.

The mice used in the titrations are injected intraperitoneally with 0.5 ml. of a 0.5 per cent solution

Fig. 1. Pancreatic staining in normal and infected mice. Infected pancreas stains deep blue, normal pancreas remains pink. 1 and 2, Connecticut 5; 3, normal; 4 and 5, Nancy

of trypan blue in saline, four days after inoculation with virus. When mice are killed four hours after injection with the dye, the pancreas in infected animals is found to be stained intensely (Fig. 1). In most cases intense dark blue staining of a large part of the pancreas is found, and in the remainder, lighter blue areas of varying size are seen. Staining may be demonstrated from two days after inoculation with virus, and increases rapidly in intensity. Maximum intensity of staining is reached within four days, and is retained for several days. These results were obtained by investigation of the influence of virus dosage and time on the degree of staining, and showed that the most suitable (shortest) time between inoculation with virus and injection with dye in titrations is four days.

In the accompanying table, results of five parallel titrations in mice 21–24 days old of a single pool of a Group B strain (Adelaide 1) by two methods are presented. The 'conventional' LD50 and ID50 titres were calculated by the method of Reed and Muench² from the number of deaths which occurred within three weeks and the number of survivors which had suffered fat replacement of pancreatic acinar tissue.

The titre determined by the intravital staining technique was found to agree closely with the LD50 titre; the 'conventional' ID50 titre was slightly higher. The latter observation suggests that, in a small proportion of infected mice, pancreatic necrosis is not revealed by intravital staining, either as a result of delayed development of the lesion when the inoculum is small, or because not all centres of necrosis involve the surface of the pancreas.

In further experiments the technique has been shown to be suitable for use in neutralization tests, since neutralization indices of sera estimated by the above technique and by LD50 estimations agreed closely.

COMPARISON OF TITRES OF A GROUP B VIRUS BY TWO TECHNIQUES

Titration number	Conventional technique		Intra-vital staining technique
	LD50	ID50	ID50
1	4.75*	5.22	4.63
2	5.17	5.50	5.37
3	4.96	5.17	4.67
4	5.06	5.24	5.37
5	4.33	4.33	4.75
Mean	5.02	5.23	5.00
Standard deviation	0.41	0.28	0.34

* Titres are expressed as their negative logarithms.

The techniques almost universally adopted for the titration of Coxsackie viruses, and for the detection of neutralizing antibodies against them, employ suckling mice inoculated within a few days of birth*. When suckling mice are used, non-specific deaths and cannibalism of sick mice are relatively common. In Group B infections with pancreatotropic strains, the main signs of infection (oedema, weakness and cyanosis) may also be seen in mice dying from non-specific causes. Also, maintenance of an adequate supply of litters may be difficult, particularly in small laboratories. The technique described overcomes many difficulties by allowing the use of weaned instead of suckling mice; by reducing the time taken in titrations from three weeks to four days—in itself desirable—accommodation problems are alleviated, and much of the time normally spent in the daily examination of mice is saved. The method would be particularly valuable in large-scale screening tests of sera for neutralizing antibodies, and is at present being used successfully in this laboratory for that purpose.

To date the technique has been successfully applied to three Group B strains, namely, Connecticut 5, Nancy, and Adelaide 1, representing three serological types. Although pathogenicity of Group B strains for weaned and adult mice has not been widely reported, Dalldorf⁴ has recently presented evidence that this may be due to differences in the methods used for virus passage rather than to differences in susceptibility of different mouse strains. The technique may therefore be more widely applicable than at first appeared possible. A more detailed account of this work will be published elsewhere.

Chromosome Number of Human Endometrium

The determination of chromosome number in human somatic tissues has been the cause of controversy from time to time. Recently, Timonen¹ made an extensive study on the variations of the chromosome number in the human endometrium in the proliferative stage. From a study of one thousand nuclei, he finds that the highest frequency distribution is between 21 and 25 chromosomes. This result has been criticized by Sachs²; the number obtained by him from the same tissue of human beings and from other mammals corresponds to the diploid number of the particular species concerned.

For some time past, I have been studying the chromosome number in human endometrium and also in the epithelial cells of the cervix uteri both in normal and in malignant conditions. The present communication is based on the study of the chromosomes of the human endometrium in the proliferative stage.

Human endometrial tissue immediately after removal was cut into small pieces and was transferred to 0.002–0.005 M oxyquinoline solution³ for 2 hr. at 16°C., after which it was fixed either in acetic

Fig. 1. Metaphase chromosomes of human endometrium. ($\times 1,000$)

alcohol for Feulgen squash or was subjected to the aceto-carmine technique. As a result of the pre-treatment, the chromosomes are more or less straightened, and the centromeric region and the split between the chromatids of the individual chromosome are exaggerated (Fig. 1). Squashing may also cause cellular damage, as pointed out by Sachs². Doubtful cases have therefore been avoided so far as practicable.

The chromosome number counted in the different cells of my material varies from 30 to 59 chromosomes (Fig. 2). Of 75 nuclei counted, 15 had 48 chromosomes and 37 had chromosome numbers ranging from 40 to 47; of the latter, 33 nuclei had 40–45 chromosomes. Twenty nuclei had chromosomes ranging from 30 to 39, of which 14 had 36–39 chromosomes. Three nuclei had 54, 55 and 59 chromosomes respectively. My observations, therefore, support Timonen's conclusion regarding the variability of the chromosome numbers between different cells, but the range and characteristics of variation observed by him are not found in my material. My unpublished observations on the chromosome numbers in human uterine cervix tissue also support Timonen's conclusion regarding the variability of chromosome numbers in human somatic tissue.

Thus, it now appears fairly certain that the chromosome numbers vary widely between different cells of the same tissue as well as between different tissues, not only in human beings but also in other mammals. That this is due to the presence of mitotic abnormalities such as lagging, non-disjunction, multipolar spindle, etc., in the tissue is also clear. Admittedly, human tissue is difficult material for chromosome counts; but the differences in results reported by Timonen, Sachs and myself can scarcely be due to technique alone. There must be some other real source of variation which would account for the differences. It seems to me that two factors may play an important part in the production of a particular frequency distribution of chromosome

Fig. 2. Frequency distribution of chromosome numbers

number in a particular tissue. They are: (i) mitotic age of the tissue; and (ii) frequency of mitotic abnormalities originally present in the tissue. Gopal-Ayengar³ has reported a very significant observation which supports this hypothesis. He finds, in his study of transplanted tumours in several strains of mice and rats and in the Chinese and golden hamsters, that the cell population of early transplanted generations of tumours are almost entirely diploid, whereas later transplants have diploid, triploid and intermediate types exhibiting a gradual shift to tetraploidy.

I am indebted to Dr. Subodh Mitra, director of the Chittaranjan Cancer Hospital, Calcutta, for providing laboratory facilities and for his interest, and to Dr. S. P. Ray-Chaudhuri, of the University of Calcutta, for his guidance during the course of investigation.

Physiology of the Heart of *Asellus aquaticus* L.

WORK on this subject was carried out some years ago, on nearly three hundred intact individuals and heart preparations, the latter consisting of heart, pericardium and dorsal body-wall of the thoracic region. The heart-rate of an average (10 mm.) individual at summer temperature was 180–200 per min., but heart-beat was interrupted for short periods, for example, at the onset of a burst of locomotor activity. Dissection of the preparation always slowed and sometimes arrested the beat for periods up to 30 min. On recovery, the beat was regular and incessant, often at the maximal normal rate.

Mechanical and electrical stimulation revealed an accelerator nerve following the anterior aorta, undoubtedly the anterior nerve of Alexandrowicz¹. Transection of the ventral nerve cord just behind the head regularly slowed the heart *in situ*. Transection of the anterior aorta in this region had little effect, and transection of the ventral nerve cord farther back had progressively less effect. Section of the anterior thoracic segmental nerves also had little effect; but cutting those of posterior segments, or damage to the abdominal ganglia, often (not always) caused temporary arrest—probably an injury-stimulation of cardio-inhibitory fibres.

Faradic stimulation of the preparation accelerated the beat, which synchronized with the stimulus at moderate rates of acceleration. Increasing rate progressively shortened systole, until complete diastolic 'amplitude-arrest'—probably tetanization of the dilator muscles². On switching off, such an arrested heart passed back through the stage of rapid flutter to its normal beat. Sensitivity of the heart to faradic stimulation when applied in the aortic region was greater than when applied in the heart region itself, so that a rate of stimulation which arrested when applied in the former region, accelerated when applied in the latter. Sensitivity was much lower to faradic currents applied transversely than to those along the heart.

Relatively light pressure, localized or diffuse, to the ventral face of the floor of the pericardium caused arrest, its duration proportional to intensity of stimulation; a local reflex inhibition seems indicated. Moderate traction dorsalwards of the roof of the pericardium (that is, the body-wall) usually accelerated the heart-rate, and the volume of the pericardium may be the critical factor. Excessive traction inhibited heart-beat.

Asynchrony between the two ends of the heart was observed after transection of the dorsal heart-wall³, and often in moribund preparations. Sometimes asynchrony between the lateral halves was observed; on occasion one half, longitudinal or lateral, was completely quiescent. Complete asynchrony of all muscle fibres—the 'bag of worms' type of fibrillation—was produced by excess sodium chloride and possibly by other conditions. Activity of aortic valves and ostia showed some independence of that of the myocardium, as expected from their innervation¹; but in recovery from arrest, activity often began in the ostia and spread to the myocardium.

The optimal concentration of sodium chloride for survival appeared to be 0.6 per cent, that is, lower than that used by Kawaguti⁴ for *A. nipponensis*. Preparations survived up to 48 hours in 0.6 per cent sodium chloride, 0.02 per cent potassium chloride, 0.02 per cent calcium chloride, 0.02 per cent sodium bicarbonate, and 0.2 per cent glucose. Excess calcium and deficit of potassium ions slowed or arrested the heart in diastole. Excess potassium ions accelerated, with diastolic amplitude-arrest as the limit; exoskeletal calcium ions probably prevented effective calcium-deficit, and calcium-free Ringer's solution had little effect. Magnesium, beryllium and hydrogen ions slowed, to arrest in diastole. Acetyl-choline accelerated in relatively high concentration⁵. Adrenalin had no consistent effect. Inhibition by the animal's own digestive fluid⁶ was confirmed; mammalian lipase and trypsin similarly inhibited.

The curve relating temperature centigrade (T) (changed gradually) to beat-interval (t), that is, to the reciprocal of rate, was approximately a rectangular hyperbola $(t + a)(T + b) = c$, where a , b , c are constants. Thus there was an upper limiting rate and a lower limiting temperature, a 'physiological zero', at which the beat virtually ceased. This varied between $+4^\circ$ and -4° C. (obtained by supercooling), in different individuals, but was usually below 0° C. Maximal rate was attained at 25 – 35° C., that is, again variable between individuals; above this temperature there were irregularities and slowing of the beat. Since a was small (less than 0.5 sec.) a virtually linear relationship between rate and T was often obtained, and it follows also that $(\log t)/(\log (T + b))$ was virtually linear. Preparations frozen by seeding the supercooled medium recovered their beat on thawing.

ROYAL AERONAUTICAL SOCIETY (at the Institution of Mechanical Engineers, Storey's Gate, London, S.W.1), at 6 p.m.—Dr. D. Williams: "Recent Developments in the Structural Approach to Aeroblastic problems".

UNIVERSITY OF LONDON (at Wye College, near Ashford, Kent), at 15 p.m.—Mr. H. M. Nicholson: "The Nature Conservancy".*

Friday, February 12

ROYAL ASTRONOMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Anniversary Meeting; Annual General Meeting.

INSTITUTION OF MECHANICAL ENGINEERS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 5.30 p.m.—Third Report of the Pe Flanges Research Committee, presented by Dr. A. B. Johnson.

ARLIS (at the Royal Society of Arts, 8 John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Mr. C. W. Hanson and Mr. C. H. O. Swenson: "Journal Circulation: An Enquiry into the Practice".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. C. Keith Simpson: "Science in Crime Detection".

Saturday, February 13

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (Joint meeting with the ASSOCIATION OF CHEMICAL BIOCHEMISTS, S.H. and S.W. REASON, in the Department of Zoology, The University, Reading), at 2.30 p.m.—Papers and Demonstrations on "Physical Methods in Biochemistry".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

SENIOR SCIENTIFIC OFFICER (with first- or second-class honours degree in chemistry or a biological subject, or approved equivalent professional qualifications, and at least three years postgraduate or other approved experience), and an EXPERIMENTAL OFFICER (with a degree in an approved scientific subject, or equivalent professional qualifications), in the Combined Scientific Development and Forensic Science Department of the Ministry of Commerce—The Secretary, Civil Service Commission, Stormont, Belfast (February 12).

SENIOR TECHNICIAN (with knowledge of E.H.T. and pulse circuits for Geiger and scintillation counting) for maintenance and development of electronic equipment—The Secretary, Board of Governors, Hammar-smith Hospital and Postgraduate Medical School, Du Cane Road, London, W.12 (February 13).

LECTURER (with qualifications in cytology, genetics and plant breeding, and with teaching and research experience in these subjects) in BOTANY—The Secretary, The University, Aberdeen (February 15).

LECTURER (with a degree or a recognized diploma in mining) in the DEPARTMENT OF MINING AND GEOLOGY, and a LECTURER (with an honours degree in physics, and preferably with teaching, industrial, or research experience) in PHYSICS—The Principal, Wigan and District Mining and Technical College, Wigan (February 15).

ASSISTANT LECTURER in the DEPARTMENT OF CHEMISTRY, and an ASSISTANT LECTURER in the DEPARTMENT OF PHYSICS—The Secretary, Bedford College, Regent's Park, London, N.W.1 (February 19).

SENIOR PHYSICIST (with an honours degree in physics, and five years previous experience in hospital physics or research, and preferably with a practical knowledge of radio-elements)—The Secretary, Lambeth Group Hospital Management Committee, Renfrew Road, London, S.E.11 (February 19).

ASSISTANT LECTURER (with special qualifications in physical chemistry or in physical organic chemistry) in the DEPARTMENT OF CHEMISTRY—The Registrar, University College of South Wales and Monmouth, Cathays Park, Cardiff (February 20).

ASSISTANT LECTURER in CHEMISTRY—The Registrar, University College, Singleton Park, Swansea (February 27).

CHIEF CHAIR OF METALLURGY—The Registrar, The University, Nottingham (March 1).

PROFESSOR OF PHYSIOLOGY at the University of Cape Town, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Cape Town, March 1).

UNIVERSITY DEMONSTRATOR in AGRICULTURAL ZOOLOGY AND PHYSIOLOGY OF FARM ANIMALS, a UNIVERSITY DEMONSTRATOR in SOIL SCIENCE, a UNIVERSITY LECTURER in AGRICULTURAL ZOOLOGY AND PHYSIOLOGY OF FARM ANIMALS, and a UNIVERSITY DEMONSTRATOR in AGRICULTURAL BOTANY—The Secretary, School of Agriculture, Downing Street, Cambridge (March 6).

ASSISTANT LECTURER in PHYSICS, and an ASSISTANT LECTURER in THEORETICAL PHYSICS—The Registrar, King's College, Strand, London, W.C.2 (March 6).

CHAIR OF GEOGRAPHY—The Registrar, University College, Leicester (March 6).

LECTURER in CHEMISTRY, a DEMONSTRATOR in BIOCHEMISTRY, and a DEMONSTRATOR in CHEMISTRY, in the Department of Biochemistry and Chemistry—The Dean of the Medical College, St. Bartholomew's Hospital, West Smithfield, London, E.C.1 (March 6).

LECTURER (with an honours degree in mechanical engineering, and special experience of mechanical engineering drawing and design theory of machines and strength of materials) in MECHANICAL ENGINEERING, at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Sydney, March 7).

LECTURER in PHILOSOPHY at the University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Johannesburg, March 31).

I.C.I. RESEARCH FELLOWSHIPS in PHYSICS, CHEMISTRY, BIOCHEMISTRY, ENGINEERING, METALLURGY, PHARMACOLOGY, CHEMOTHERAPY, or related subjects—The Secretary General of the Facilities, The Old School, Cambridge (April 30).

TURNER AND NEWALL RESEARCH FELLOWSHIPS for research in ENGINEERING, INORGANIC CHEMISTRY, PHYSICS, and allied subjects—The Registrar, The University, Manchester 13 (April 30).

JUNIOR LECTURER in the DEPARTMENT OF ENTOMOLOGY—The Assistant Dean, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1 (June 1).

AGRICULTURAL OFFICER (with a degree or diploma in agriculture or allied subjects), at Dunholme Field Station, near Lincoln, for duties which will include organizing field experiments, and assisting with research work on sugar beet—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

CHAIR OF EDUCATION—The Registrar, The University, Sheffield.
DIRECTOR OF THE BHARAT SAHNI INSTITUTE OF PALAEBOTANY, to take charge of the administration of the Institute, and to conduct and supervise research—The President, Governing Body of the Palaeobotanical Society, Bharat Sahni Institute of Palaeobotany, Lucknow, U.P., India.

EXPERIMENTAL OFFICER or ASSISTANT EXPERIMENTAL OFFICER (with at least higher national certificate or equivalent and a thorough knowledge of basic radio and electronics) in the TIME DEPARTMENT, Royal Greenwich Observatory, Abingdon, for maintenance and installation of operational equipment of time service.—The Ministry of Labour and National Service, Technical and Scientific Register (R), 20 King Street, London, S.W.1, quoting D.9/54A.

GEOLGISTS (with first- or good second-class honours degree in geology) in Malaya, for investigations of mineral resources and detailed geological mapping.—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting ODH.106/60/03.

MICROBIOLOGIST (with a first- or good second-class honours degree in an appropriate subject, and with at least two years postgraduate experience in soil microbiology) in the East African Agricultural and Forestry Research Organization, to take charge of new Soil Microbiological Section.—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting ODH.87/53/02.

PHYSICIST or ELECTRICAL ENGINEER (with at least H.S.C. (science), or equivalent, and preferably with experience of experimental work using electronic equipment), at the Ministry of Supply Radar Research Establishment, Malvern, to work on problems of packaging of electronic equipment, involving investigation of cushioning systems under simulated service hazards, and design of shock suspension systems for items of radar equipment having special packaging problems.—The Ministry of Labour and National Service, Technical and Scientific Register (R), 20 King Street, London, S.W.1, quoting A.8/54A.

PHYSICIST (with an honours degree in physics), to carry out fundamental investigations connected with new methods of casting steel by continuous processes.—The Personnel Officer, British Iron and Steel Research Association, 11 Park Lane, London, W.1, quoting "Casting".

PHYSICIST (with mathematical leanings) for experimental work on fibre assemblies.—The Secretary, British Rayon Research Association, Barton Dock Road, Urmston, Manchester.

PROFESSOR OF PHYSICS at the College of Arts and Science, Baghdad.—The Cultural Attaché, Iraqi Embassy, 29 Queens Gate, London, S.W.7.

SENIOR LECTURER in CHEMICAL ENGINEERING at the Technical College, Bradford.—The Director of Education, Town Hall, Bradford.

PHYSICIST REQUIRED TO CONTROL THE yuca section of a research and development laboratory. Applicant would be required to work with chemists, metallurgists, and ceramists in developing a variety of semi-conductors, ferroelectric and ferromagnetic materials for the electronic, radio and radar industries. Measurements of the basic properties of these materials would be an important part of the work. Applicants should have either an honours degree in physics with a minimum of three years' experience, or a Ph.D. salary will depend on experience and qualifications.—Box 837, T. G. Scott & Son, Ltd., 143-147 Regent Street, London, W.1.

GLAXO LABORATORIES, LTD., REQUIRE young Biochemist (male) in the Process Investigation Department at their Ulverston antibiotic factory. Applicants should hold good honours degree, with biochemistry as principal subject. A title experience in academic research or industry is desirable. Participation in pension and incentive bonus schemes after six months' satisfactory service.—Apply, in writing, to Senior Personnel Officer, Glaxo Laboratories, Ltd., Greenford, Wiltshire.

THE MULLARD RADIO VALVE COMPANY

HAS A VACANCY.

in its

VACUUM PHYSICS LABORATORY

for an

ELECTRONIC ENGINEER

to be responsible for the design of electronic circuits in support of the programme of Special Valve research and development.

The subjects involved are many but principally involve digital computing, pulse generation and modulators, V H F and U H F techniques.

The position is one of responsibility calling for a first-grade man of independent thought and initiative.

Candidates should be honours graduates with at least three years' experience in one or more of the above subjects.

Apply in the first instance to
Mr. G. A. TAYLOR
Personnel Officer
Mullard Research Laboratories,
Cross Oak Lane,
Salford, near Redhill, Surrey

A GRADUATE WHO HAS READ CHEMISTRY or Physics is required for the management staff of a nationally known company. Two further graduates will be required later in the year and any interested applicant not immediately available is invited to consider this opportunity as the company is engaged in light chemical processing and production at its establishments in various parts of the country and has managerial vacancies which necessitate a technical background. These positions appeal to the graduate who wishes to avoid a purely technical career and desires to progress in a field combining management of people with technicalities. Over the past twenty years the company has met its expansion needs by an introduction of graduates into such positions, on which they have made progress into higher level executive positions. Adequate training will be given and this will be carefully supervised by senior graduate members, who will see that the new man takes over his first responsibilities with confidence. Continuing company growth provides growing opportunities for advancement and since senior positions are filled from within, the company is keenly interested in seeing its younger men develop into greater responsibilities. These could even be in other fields of company operations, depending upon the ability and aptitude of a man. The company maintains a high standard of salaries, increments, superannuation, etc., and would wish suitable candidates to have an opportunity of seeing something of its operations before its decision on either side. Strict confidence will be observed in any dealings with applicants. Please forward outline of background to date to Box 838, T. G. Scott & Son, Ltd., 143-147 Regent Street, London, W.1.

APPOINTMENTS WANTED

PHYSICIST, 29, PH.D., SEVEN YEARS' EXPERIENCE industry and research, two years editor, seeks post. Salary about £900 London area.—Box 830, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

APPLIED MATHEMATICIAN, HONOURS degree, four years' research experience, age 25, seeks research (and possibly teaching) position.—Box 841, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

GRANTS & SCHOLARSHIPS

UNIVERSITY OF LEEDS

Applications are invited for Imperial Chemical Industries, Limited, Research Fellowships in bacteriology, biochemistry, biomolecular structure, botany (plant biochemistry and biophysics), chemical engineering, chemistry, chemistry of leather manufacture, chemotherapy, colour chemistry and dyeing, engineering (civil, electrical or mechanical), fuel and refractories, geology (including geochemistry), metallurgy, mining (selective flotation and geophysical surveying), pharmacology, physics, physiology or textile industries (protein chemistry and wool textile engineering). The Fellowships will be of an annual value within the range £600 to £900 a year, according to qualifications and experience, and will normally be tenable for three years.

Further particulars can be obtained on request. Three copies of applications (one in the case of applicants from overseas), together with the names of two referees, should reach the Registrar, The University, Leeds, 2, not later than April 21, 1954.

EMPIRE COTTON GROWING CORPORATION

POSTGRADUATE STUDENTSHIPS, 1954-5

With a view to subsequent appointment to the overseas staff, men who have completed their National Service are invited to apply for studentships in: Applied Genetics and Plant Breeding, Entomology, Plant Pathology, Crop Physiology. Training will be at British Universities, with grants ranging according to location from £25 to £34 10s a month, plus approved fees and other allowances. Starting salary in the Corporation's service is not less than £700 per annum, including cost of living allowance, with free housing and passages.

Details and application forms from the Secretary, Empire Cotton Growing Corporation 12 Chancery House, Eccleston Street, London, S.W.1.

UNIVERSITY OF NOTTINGHAM DEPARTMENT OF MECHANICAL ENGINEERING

Applications are invited for the British Rubber Producers' Research Fellowship, value up to £500 per annum. The Fellowship has been instituted to encourage research into the mechanical properties of rubber. Applicants should have a good honours degree in engineering or physics, and industrial or research experience.

Full particulars and application form may be obtained from the Registrar, University of Nottingham, to whom applications should be submitted as soon as possible.

UNIVERSITY OF CAMBRIDGE I.C.I. FELLOWSHIPS

Applications are invited for Research Fellowships, value within the range £600 to £900 a year, founded by Imperial Chemical Industries, Ltd., tenable in the University and available for research in physics, chemistry, biochemistry, engineering, metallurgy, pharmacology, chemotherapy, or related subjects. Applications must be received not later than April 30, 1954.

Regulations governing the award of the Fellowships may be obtained from the Secretary General of the Faculties, The Old Schools, Cambridge, to whom all applications should be addressed.

McMASTER UNIVERSITY POSTDOCTORATE FELLOWSHIPS IN PHYSICS AND CHEMISTRY

Applications are invited for postdoctorate fellowships in the fields of (a) theoretical nuclear physics (M. A. Preston), (b) mass spectrometric studies in geophysics and geochemistry (H. G. Thode) and (c) atomic mass determinations (H. E. Duckworth).

Interested persons should write as soon as possible to Professor H. E. Duckworth, Department of Physics, Hamilton College, McMaster University, Hamilton, Ontario, Canada.

UNIVERSITY OF LIVERPOOL

Applications are invited for I.C.I. Research Fellowships in physics, chemistry, engineering, metallurgy, and pharmacology, or any related subject, to which some appointments may be made during the current academic year. The appointments will date from October 1, 1954 or earlier in the case of selected candidates who may be available before that date. The salary will depend upon qualifications and experience, but will normally be within the range £600 to £900 per annum, together with F.S.S.U. benefits and family allowances.

Applications (three copies), with a list of publications and the names of two referees, should be received not later than March 1, 1954, by the undersigned, from whom further particulars may be obtained. (Candidates overseas, who find it more convenient to do so, may send one copy only by airmail.)

STANLEY DUMBELL,
Registrar

SCHOLARSHIPS ABROAD, 1954-55

Applications are invited from British students for scholarships offered by Austria, Belgium, Brazil, Denmark, Finland, France, Germany, Iceland, Italy, The Netherlands, Norway, Portugal, Spain, Sweden, Switzerland and Yugoslavia. The awards are mainly for university graduates and undergraduates, and are tenable for periods varying from four to twelve months during the academic year 1954/55. The closing date for receipt of applications varies for each country, the earliest being March 8, 1954.

Full particulars and application forms are obtained on receipt of a stamped, addressed foolscap envelope from the British Council, 65 Davies Street, London, W.1, or from any British Council office in the United Kingdom.

BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH

Notice is hereby given that an election of Junior Fellows to begin work on October 1 next will take place in May, 1954. Junior Fellowships are of the annual value of £630 for three years. As a rule, superannuation benefits are provided, to which the successful candidates will be required to contribute 5 per cent of the annual stipend, and to which the Trust will make a contribution of 10 per cent. Candidates must have taken a degree in a faculty of a university approved by the Trustees in Her Majesty's Dominions, Protectorates and Mandated Territories, India, Pakistan and the Republic of Ireland, or a medical diploma registrable in the United Kingdom. Elections to Junior Fellowships are rarely made above the age of 35 years. Applications from candidates must be received not later than April 1, 1954. Candidates must submit evidence that they can be given accommodation in the departments where they propose to work, which must be either in Great Britain or Ireland.

Forms of application and all information may be obtained, by letter only, addressed to the Secretary, Beit Memorial Fellowships for Medical Research, The Lister Institute, Chelsea Bridge Road, London, S.W.1. For overseas candidates forms of application may be obtained from the Secretary, South African Medical Council, P.O. Box 205, Pretoria, South Africa; The Director, Commonwealth Office of Education, Box 3879, Sydney, Australia; The Department of Health, Wellington, New Zealand; and the Canadian Medical Association, 184 College Street, Toronto, Canada.

FOR SALE AND WANTED

FLAME PHOTOMETER MODEL 1B BY Process and Instruments Inc. Imported under licence, 1952. 110-250 v Suitable for absolute and lithium internal standard determinations. Operates on propane and compressed air. Complete, with compressor, 230 v A.C., £400. May be viewed by appointment.—Box 829, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

REQUIRED AT ONCE, ABBE REFRACTOMETER and Polarimeter.—Please state make and age and price to Box 831 T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

FOR SALE, "SCIENCE OF PETROLEUM," 4 vols., £7. "Atlas Metallurgica," Vol. 1, Publisher's quarter-binding, £10.—A. L. Roberts, 4 Victoria Street, Shrewsbury

REQUIRED: SUBSTANTIAL RUN OF Liebig's "Annalen"—Condition and price to Box 840, T. G. Scott and Son, Ltd., 143-147 Regent Street, London, W.1.

FOR PHOTOMICROGRAPHY

BECK TENSLITE LAMP

Projectolux Camera

The new Projectolux Camera is eminently suitable for magnifications from twenty-five diameters to the highest powers. The correct and permanent alignment of the lighting system will be found invaluable by the busy worker.

Please write for copies of our new Catalogue Supplements, including the 'Projectolux Camera'

*"To the solid ground
Of nature trusts the Mind that builds for aye."—Wordsworth*

VOL. 173, No. 4398

SATURDAY, FEBRUARY 13, 1954

TWO SHILLINGS

THE **NEWTON**

LONG WORKING DISTANCE ATTACHMENT

... provides a working distance of 12.8 mm. between object glass and specimen when fitted to a standard microscope in conjunction with a conventional 4 or 8 mm. objective.

A further important feature is that the use of this attachment eliminates image reversal and thus further facilitates examination and manipulation of specimens.

BAKER

SCREW MICROMETER EYEPIECE

In this eyepiece a fine line is made to traverse the field of view by means of an accurate screw. The drum controlling the movement is divided into 100 parts, each representing 0.01 mm. displacement of the line. Evaluation is effected by the use of a stage micrometer ruling; the value of the divisions of the drum depending upon the magnification. In lined case, £15.

VACUUM NOTES: No 9

Choosing a vacuum gauge

(a) The McLeod Gauge

Invented as far back as 1874, the McLeod Gauge is still the standard reference gauge. It is the simplest and most accurate type for laboratory use, but it must be appreciated that it has its limitations; it cannot measure condensable vapours and does not lend itself to industrial work where remote or continuous indication is necessary. For such conditions other types of gauge would have to be used—and the correct choice is part of the "know-how" of high vacuum technique. Edwards experience and knowledge is freely available to vacuum users.

for better vacuum service...

LEEDS & NORTHRUP MICROMAX & SPEEDOMAX INSTRUMENTS

We supply balance-type Instruments for Temperature (thermocouples, electrical resistance thermometers, radiation elements), pH Conductivity, Speed, Voltage, Current and Load, etc.

For Automatic Operation: Micromax and Speedomax Indicating, recording and controlling Instruments are available.

Strip-Chart Micromax records up to 16 points on a wide, easily-read chart; Indicates on a straight scale. Can operate signals and controls.

Round-Chart Micromax Indicates on a circular scale; records one or two points on a 24-hour chart. Can operate signals and most controls.

For use where a record is not needed, we supply a *Micromax Indicating Controller*. Also available is a non-Indicating model for simple, two-position control.

Speedomax Type G records from one to 16 points with unusual speed; can operate controls. *Strip-chart model* records in detail; also Indicates. *Round-chart model* Indicates boldly; records on 24-hour chart. (Type A, primarily for the lab., provides extreme speed.)

Speedomax Type G Indicator Indicates up to 100 points faster than ever before.

For Manual Operation: *Panel indicators*, with selector switches, enable operator to measure successively, from one central location, points at widely scattered locations. *Portable indicators* are light enough to carry easily for checking anywhere in the plant.

Checking Instruments, with ranges and accuracies for all plant and laboratory tests.

AGE-LIMITS AND WORKING LIFE

THE National Advisory Committee on the Employment of Older Men and Women was appointed in March 1952, "to advise and assist the Minister of Labour and National Service in promoting the employment of older men and women". Under the chairmanship of Mr. H. Watkinson, Parliamentary Secretary to the Ministry of Labour and National Service, the Committee has taken this as an instruction to consider what conditions or circumstances hinder the employment of older persons and what are most likely to help. Its aim is to suggest the general lines on which the Government and public and private bodies may work together to enable and encourage men and women in all kinds of employment to use their skills and experience to a greater age, with benefit both to their own well-being and to the national economy.

The Committee's first report*, which has just been issued, shows that it is fully alive to the two main trends in Great Britain which give the employment of older men and women its present national importance—the changing age-structure of the population and the greater expectancy of life—and to the repercussions on personal life and on the national economy which are involved. Both considerations are kept in mind throughout this report; but, although since the Committee was appointed there has been a certain amount of piecemeal action to encourage the elderly to remain longer at work—some, but not all, of which is mentioned in the report—the Committee is wise in this first report to attempt to set forth the main considerations which require general discussion. It is convinced that the principal barrier to the extended employment of older persons lies in traditional attitudes of mind, which only a clearer understanding of the issues is likely to change.

The able statement of the national problem, which embraces consideration of economic and financial aspects beyond the scope of the Watkinson Committee and coming within the terms of reference of the Committee appointed by the Chancellor of the Exchequer "to review such problems in relation to provision for old age", with which Committee the Watkinson Committee expects to work in close co-operation, is an excellent contribution to that end. Its analysis of the changing age-structure and of the implications of working capacity in a longer life supplements admirably the lecture which Sir Frederic Bartlett gave two years ago (see *Nature*, 171, 623; 1953), and the Committee's brief remarks on present and future man-power needs have since received strong support in an address which Sir Godfrey Ince, Permanent Secretary to the Ministry of Labour and National Service, delivered to the Manchester Statistical Society on November 11. The Committee points out that, whereas in 1911 one in fifteen of the population of Great Britain was a man of sixty-five and more or a woman of sixty and more, in 1951 the proportion had doubled, and in 1977 it is estimated

* National Advisory Committee on the Employment of Older Men and Women. First Report. Pp. 62. (Omd. 8965.) (London: H.M. Stationery Office, 1953.) 2s. net.

as likely to be nearly three in fifteen. Of the 1951 total, two million were men aged 65-69 inclusive, or women aged 60-64. Moreover, the proportion of older people in the working population is also rising. Between 1952 and 1962 the population between the ages of twenty and forty is expected to decrease by about 7 per cent, and that between 50 and 60 to increase by about 17 per cent. By 1982, men aged 18-40 inclusive will be nearly 300,000 fewer than in 1952, and since on men in this age group the armed forces, the police, the fire services and all the occupations for which full vigour and activity are essential must have first claim, other occupations must employ a smaller proportion of them.

On this ground alone it is essential for all employers to make the fullest use of the abilities of older people below pensionable age, and also to employ to the best advantage those beyond pensionable age who are both able and willing to continue at work. Economic considerations enforce the argument. The increase in the proportion of older persons in the population means an increase in the amount of current production required for their maintenance; and the effect on standards of living may be greater should this increase not be offset both by advances in productivity and technical development and by the fullest possible utilization of the services of those able and willing to continue to be productive. No reliable estimate is as yet available of the numbers in Great Britain who might be available if they had the opportunity: at present some 400,000 men out of 850,000 in the 65-69 age group and 250,000 out of 1,250,000 in the over-70 age group are continuing at work, and the Ministry of Pensions and National Insurance is conducting a comprehensive inquiry on the Committee's behalf into the reasons influencing the individual's decision to retire or not; this should assist later in arriving at a reasonable approximation.

The Committee recognizes the need for more research into the process of ageing, and into the differing skills and abilities demanded by particular occupations; but its report adds little to what Sir Frederic Bartlett said on this point. Its argument, however, is strongly supported by evidence provided in the latest report from the Chief Inspector of Factories, in which Sir George Barnett emphasized that while the consequences of accidents to older people tend to be more serious, they do not appear to be more prone to accidents. Many are apparently able to exercise in industry the skill acquired in a life-time unaffected by advancing years. Here, again, more precise information is required before positive conclusions can be reached.

It is the Committee's observation that the encouragement of the employment of older people is a present as well as a long-term need which was most strongly endorsed by Sir Godfrey Ince. If it is Government policy to maintain a high and stable level of employment for all who want to work and are fit to do so, the Committee is convinced there should be no age limit. Limitation of employment opportunities for older people who want to work is not a tolerable permanent solution for unemployment either from a human or an economic point of

view. From the short-term point of view Sir Godfrey shows that it may be disastrous.

Assuming during the next ten years a decline of only six per cent in the working population aged between twenty and forty, and an increase of 20 per cent in those aged between fifty and sixty, Sir Godfrey pointed out that the small rise in the total working population expected over the next eight years would by no means match the necessary rate of increase in production. Analysis of the four main tasks now before Great Britain, he said, shows that no immediate substantial reduction can be forecast in the demands of the defence programme: we are unlikely, therefore, to have additional man-power available to expand the capital investment programme and increase the export of engineering products. The second task is the maintenance of exports at an increasingly high level, the third to maintain home capital expenditure at a much higher level than at present and the fourth to produce sufficient consumer goods to keep up the country's standard of living.

These formidable and essential tasks can only be carried out, said Sir Godfrey, apart from some unforeseen change in the general economic situation, by increasing production and particularly by the more efficient use of man-power. Apart from the modernization, improvement and extension of plant, machinery and mechanical power, this will involve the distribution of man-power so that the maximum number of workers are in the right jobs, in the right districts at the right time, more careful training of recruits and existing workers and the establishment of good human relationships in industry. Even so, it is probable that the Armed Forces will have considerable difficulty in recruiting the man-power they need.

The corollary of Sir Godfrey Ince's address is clear: not merely must there be more mobility of labour and the general abandonment of restrictive practices and national habits on the part of industry and business, including the trade unions; there must also be much more flexibility and fresh thinking about retirement, production and employment generally. A new attitude may be required in which the approach is expressed not by 'no men over forty need apply', but rather 'no man under forty need apply'. There are manifestly jobs in industry and commerce in the broadest sense in which the employment of fit men under forty is a disservice to the State.

The Watkinson Committee's observations on engagement and retirement policy, on professional, managerial and executive employment, and on pension schemes, and its tentative recommendations should be considered in the light of such a change of outlook. The Committee insists that the test for engagement should be capacity and not age, and urges that retirement policy should be such that all men and women employed in industry, commerce, the professions and elsewhere, who can give effective service, either in their normal work or in any alternative work which their employers can make available, should be given the opportunity, without regard to age, to continue at work if they so wish. The main difficulties in

giving effect to these principles are found among the professional, managerial and executive classes; but it is here that the Committee believes that unnecessary waste of ability, qualifications and experience is most likely. Moreover, the shortening of the span of working life of the professional classes and certain others in the higher ranges of employment in this century, due to the lengthening of professional training and to earlier retirement on pension, represents a real loss of public and private investment.

The Committee does not underrate the difficulties, but it rightly urges that there should be more flexibility in regard to salary scales, promotion systems and superannuation schemes. The difficulties are a challenge to personnel management which some organizations have already met. What is required is a fresh approach to the question of the retiring age, which may avoid invidious decisions, and still more a greater readiness to make exceptions to it where desirable—and these exceptions should be frequent. Moreover, since pension schemes have a greater influence on the opportunities for employment among the professional and executive class than elsewhere, the modification of such schemes is a matter which concerns not merely professional workers and their own associations as well as their employers, whether industry, the Government or the universities or other bodies, but also the insurance companies with which pension schemes may be arranged. If insurance companies undertaking such business made a common fund and invited those concerns which carry their own funds to join and agree on two or three alternative forms of superannuation contract as standard, it would be easier to provide the flexibility desirable. Moreover, there would be the further important advantage that by enabling a policy holder to move from one concern to another without wasting his own or the employers' contributions, not only would it be easier to place the elderly worker in a suitable post but also throughout his career mobility would be encouraged, to the great advantage of the country as a whole.

There is need both for more information and for more thought on all these matters, as the Committee recognizes. Reference is made to some examples of changes in practice in the recruitment of older workers and in retirement policy, both in industry and in government and local government service. The Minister of Health has since pointed out that between January 1, 1952, and July 1, 1953, the number of permanent Civil servants over sixty years of age increased from 18,781 to 29,208, although there has been a simultaneous decrease of 25,460 in the size of the Civil Service. The Life Offices Association has since issued a statement indicating three ways of designing pension schemes which should eliminate employers' objections, on superannuation grounds, to employing older men. In the University of Oxford, motions to raise the retiring age of all teaching and administrative staff were approved by Congregation on November 3, and on the same day a debate at a meeting of the Senate of the University of Cambridge on a report from the Council on the question of retirement indicated that, while there were diverse

views on the question of retiring age, the importance of making greater use of the services of retired officers or teachers was fully appreciated.

The Watkinson Committee deprecates any attempt to move too fast. This first report is intended rather to provoke discussion and to stimulate thought about the various difficulties which questions of promotion and pension schemes present; and to encourage the initiation of further inquiries into fitness and capacity for work at later ages, into the productivity of older workers in comparison with that of younger workers on various types of work, into absenteeism and time-keeping and accident-rates, into the desirability of change of occupation—perhaps with re-training in middle or later life—for men and women employed in certain jobs which may be less suitable for older workers, and into the possibility of minor adjustments in methods and conditions of work and in the design of machinery, which should be advantageous to all, but particularly to the older workers. Some such inquiries the Committee itself proposes to institute, though it will need the co-operation of research bodies and of industry. Meanwhile, this preliminary review should encourage the introduction of further experimental schemes in business and industry, and the careful discussion of the whole subject by employers, trade unions, professional associations and others concerned, above all in the light of the implication of Sir Godfrey Ince's address that we can no longer afford to assign able-bodied men to light jobs which could be performed quite as well by men past their prime.

Where the scientist and technologist are concerned, the demographic argument is strongly reinforced by the existing shortage of scientific manpower. Although the Advisory Council on Scientific Policy in its last annual report stressed the need for greater use of scientists and technologists in industry, and this has been repeatedly urged in diverse quarters and in discussions on higher technological education, no further appreciation of the situation as a whole has appeared since the report of Prof. S. Zuckerman's Standing Committee on Scientific Manpower was submitted by the Advisory Council as its own fifth report. No indication has been given regarding any action on the Zuckerman Committee's suggestions, though the position as regards science teachers appears to have deteriorated. A Productivity Team's report on the heavy chemical industry, which indicated that the ratio of technicians to operatives on the pay-roll is one to six in the United States compared with one to sixteen in Great Britain, tends to support the general impression that, on the whole, British industry does not make anything like sufficient use of trained scientific and technical man-power. Moreover, Sir Ewart Smith's outburst at the annual conference of the British Institute of Management carried the implication that not only is industry using too few highly trained engineering technologists, but also that we are not using as wisely as we might the scientific and technical man-power at our disposal.

The most efficient use of scientific man-power was considered eight years ago by the Barlow Committee on scientific staff, but its recommendations have lost

none of their force in the interval, either in Government departments, in industry or in the universities. The wise use of man-power is above all a matter for management, and it is on management that the major share of responsibility must fall for the adjustments which will ease the strain on our limited resources of man-power as the demographic trends have full effect. Of others also, in the trade unions and in professional associations, a new outlook will be demanded and a readiness to shed obsolete practices and old habits and ideas: the task is not simply one of finding and training men of the requisite ability as managers; but wise management can do something to assist those changes and processes of adjustment. The Watkinson's Committee report is a timely reminder that some hard and constructive thinking is required fairly generally in the professions, in industry, in Government departments and public corporations and in the universities; the report is likewise a useful contribution to the task of education. Last, but not least, retirement policy and the effective use of the older scientist and technologist are essential features in any adequate policy for scientific and technical man-power, of which the expansion of higher technological education and the supply of science teachers are only special aspects, though no less essential.

THE MECHANISMS OF ORGANIC REACTIONS

Structure and Mechanism in Organic Chemistry
By Prof. C. K. Ingold. (The George Fisher Baker Non-Resident Lectureship in Chemistry at Cornell University.) Pp. ix+828. (London: G. Bell and Sons, Ltd., 1953.) 77s. 6d. net.

THOUGH each monograph written by the holder of a George Fisher Baker Non-Resident Lectureship in Chemistry at Cornell University is an eagerly awaited scientific publication, Prof. C. K. Ingold's volume arouses special interest, since it is a large and fully referenced treatise which gives the first really comprehensive account of all the work with which he and his colleagues have been concerned during the past thirty years.

While Prof. Ingold makes full use of the modern contributions of wave mechanics to valency theory, he clearly shows how present theoretical conceptions are the rational outcome of a century of active research and speculation, and not just qualitative applications of approximate mathematics of recent origin. Thus, typically, when discussing aromatic structure, he points out that what are now called 'observed mesomeric energies' themselves involve interpretative factors of an arbitrary nature. Again, in discussing theories of chemical reactivity, he stresses the view that thermodynamic factors have no essential concern with reaction mechanism, but that it is essential to know, from experimental work, the complete stereochemistry of each successive phase of any reaction process.

The first four chapters deal with molecular structure and with molecular interactions. The treatment is familiar and rational to those who still believe that one of the main properties of valency electrons is

that they do have a negative electrical charge and not merely mathematical wave-functions. Welcome stress is given to knowledge of the electrical polarizability of organic molecules. Unfortunately the theory of strong electrolytes gets no mention here, for its applications, particularly in connexion with 'salt effects', are often invoked later in critical discussions of reaction velocities.

There then follows an excellent account of aromatic substitution which, with historically complete references, develops up to 1950 the interwoven electrical polarization and electrical polarizability theories which were the greatest achievements of the British organic chemists of the 1920's. A section dealing with *ortho/para* ratios is particularly welcome, since here old facts and modern speculations are often at variance.

Aliphatic substitution processes, elimination reactions and molecular rearrangements of various types receive in all about four hundred pages of detailed discussion. The substantiation of the contrasted unimolecular and bimolecular types of heterolytic organic reactions is, of course, the main achievement of the school of British chemists at University College, London, and hitherto it has been very difficult for any outsider to comprehend the import of each item of experimental evidence. Now that the subject can be judged as a whole, the vital importance of reaction velocity measurements can be realized. Often it is seen that the exact magnitudes of reaction velocities are of as much importance in deciding upon reaction mechanism as are reaction orders, or the accelerating or retarding effects of substituents.

Many topics which have been, and some which still are, controversial receive discussion in these chapters; but so masterly is the logical development of the argument that it is difficult for even a critical reader to recall much of the divergent speculation of past days, or the cogent experimental evidence upon which it had been based. There are, however, significant contributions to this field of chemistry, originating outside London, which receive little or no discussion. Hammett's empirical equations relating chemical reactivity to chemical structure, and the use of 'competition factors' in connexion with the second, fast, stage of unimolecular substitution processes, are instances which I have noted. Some, but not all, of these omissions may be deliberate. For example, 'hyperconjugation' is rather pointedly treated as a second-order influence upon chemical reactivity. When reading these chapters of the finished book one can visualize its origin, with the meticulous British advocate lecturer facing his American audience and stifling minor criticisms by his sheer mass of factual information. Overwhelming evidence has been given to show that the full electronic theory of chemical reactivity, as developed from the time of Lapworth, is both more adequate and more applicable to experiment than the restricted American resonance theory.

Unfortunately, the last hundred pages of this book, dealing with acidity, catalysed reactions, and similar topics, are disappointingly incomplete, as if Prof. Ingold, having completed the review of the topics which are of personal interest to him, had decided that the remainder of theoretical organic chemistry was of minor importance. This is certainly untrue, for problems of acid-base catalysis, the roles of Lewis acids in electrophilic substitution, and synthetic applications of the generalized Claisen-type reaction

are as essential to organic chemistry as are aliphatic substitution processes. There are, however, other excellent monographs which deal with these subjects, and it is too much to expect of anyone that he should devote the time and energy to discuss the whole of the theoretical background of organic chemistry in equal detail.

Judged as a whole, "Structure and Mechanism in Organic Chemistry" is a classic of scholarship which will for a long time be regarded, in Britain at least, as the authoritative treatise upon theories of heterolytic reactions. It does mention that there are also homolytic reactions, but refrains from any discussion of them. As has been pointed out, it must be recognized that the book advocates a particular point of view; but since this is that of the scientific worker who is primarily an experimentalist it will receive the hearty approval of all who call themselves chemists. Prof. Ingold's admirers have hoped for a long time that he might eventually be induced to write a book such as this: in its detail and wealth of references it certainly surpasses all expectations, while in regard to its clarity of exposition it is typical of Prof. Ingold at the top of his form.

W. A. WATERS

SCIENCE AND RELIGION

Natural Religion and Christian Theology

By the Rev. Charles E. Raven. (The Gifford Lectures 1951, First Series: Science and Religion.) Pp. vii + 224. (Cambridge: At the University Press, 1953.) 21s. net.

THE first volume of Dr. C. E. Raven's Gifford Lectures contains a survey of the work of the early naturalists, of its relation to other scientific studies and to the general climate of thought. This historical survey is made for a theological purpose. For Dr. Raven, 'natural theology' and 'natural history' are closely linked, as they were for the great John Ray, who said "Divinity is my profession" and made it the scientific study of the organic world. Ray's attitude was characteristic of British men of science of the seventeenth century, but is not so popular now, when many see themselves as technocrats. His attitude has also been rejected by some theologians, ancient and modern. These theologians of the extreme other-worldly view, and the technocrats, of whom the Marxists are the most consistent, both take the same view of science: the first to condemn, and the second to attribute magical virtues to science. For these theologians the natural world is obscure and unintelligible, if not actually given over to the powers of darkness, and those who profess to study it must do so for greed of gain or from even worse motives. The Marxist, granted his inversion of the criteria of good and evil and the consequent changes in terminology, says the same. Both deny that there is any real natural order or any real natural world to be discovered, much less to excite wonder and admiration. Dr. Raven argues against the theologians that if they were right the doctrine of the Incarnation would be self-contradictory, as would the whole Hebrew tradition about the relation between the creatures and the Creator. He does not trouble to argue with Marxists or technocrats, but treats the scientific side of the matter historically. This is necessary because so much writing on the history of Western science puts

physics, especially experimental physics, in the foreground and all the rest dimly in the background. If you do that you practically accept the Marxist view, for experimental physics creates a world of artefacts and considers the world outside the laboratory, if at all, as analogous to that inside. Fortunately, some physicists are not mere artificers and can see that there is a natural order; otherwise there would be a disastrous split between the sciences.

The attitude of the naturalist is fundamentally religious and aesthetic, and, as Dr. Raven indicates, in all probability the first naturalists in Western Europe were the artists. It is an attitude which in its primitive form comes easily to people living under simple conditions closely linked with earth and sea and sky and the living creatures around them. Dr. Raven points to the excellent observation of Nature to be found in Chapters 38 and 39 of the Book of Job and other parts of the Old Testament. On the other hand—and this is a point he might have made more explicit—this attitude does not come at all easily to unfortunate people whose horizon is confined to the modern industrial urban conglomeration of artefacts.

Valuable features of the book are the tribute to the neglected sixteenth-century naturalist, Conrad Gesner, and to the Cambridge Platonists, who mediated between science and religion during the seventeenth century. Altogether this is a fascinating and illuminating book.

A. D. RITCHIE

A REVIEW OF THE PLANT KINGDOM

Plant Morphology

By Prof. Arthur W. Haupt. (McGraw-Hill Publications in the Botanical Sciences.) Pp. ix + 464. (London: McGraw-Hill Publishing Company, Ltd., 1953.) 64s.

THE title of Prof. Haupt's new book, while admittedly correct, is perhaps rather misleading, and plant taxonomy might have been a more appropriate title. It is a survey of the principal groups of the plant kingdom, all of which are dealt with from the point of view of structure, reproduction and development. It is intended to be used as a two-semester course, supplemented by appropriate practical work, and a good general elementary knowledge of botany is assumed. For students in Britain it should comfortably cover most of the systematic botany needed for a general degree.

The author has ranged widely over the plant kingdom and finds room to include most groups in more, or less, detail. In so doing, some will feel he has thrown his net rather too widely. Some groups, like the Isoetales, Psilotales and Laboulbeniales, or even more, the Acrasiales and Labyrinthulaceae, and, perhaps, one or two of the algal groups, might with advantage have been left out. In little more than four hundred pages, of which a good deal of the space is occupied by illustrations, there is none too much room for so large a project, and, for the type of student for which the book is intended, it might have been preferable to give a little more space to some of the larger groups. On the other hand, it may be contended that the book should be used as a reference book as well as, or perhaps rather than, a text-book, and that the inclusion of such groups as

those mentioned, if only for brief mention, is desirable. Certainly with the short but carefully selected bibliography, a student should have no difficulty in supplementing the information which he is able to obtain from this book.

It is a pleasure to pick up a new book, and an American one at that, which uses an old and familiar classification, and justifies so doing. Rhodophyceae and Phaeophyceae still serve, in place of the newer but less euphonious Rhodophyta and Phaeophyta, while few will regret that the author has not found it necessary to use the term Tracheophyta.

There are more than three hundred illustrations, of which about two-thirds are original. These illustrations, as a whole, are of high quality and form a valuable part of the book. The photographic illustrations are particularly clear.

Any reviewer might glance through Prof. Haupt's book and discover features which he did not like or on which he felt he might improve. Nor would it be difficult to direct attention to errors and to statements capable of misconstruction. To do so would be less than fair to the author. By modern standards, he has undertaken a big task and one which might have been farmed out among specialists; but in that way the book would not have achieved an individuality, and that it undoubtedly possesses. F. W. JAMES

PHYSIOLOGY OF THE ALGAE

The Metabolism of Algae

By Dr. G. E. Fogg. (Methuen's Monographs on Biological Subjects.) Pp. x+149. (London: Methuen and Co., Ltd.; New York: John Wiley and Sons, Inc., 1953.) 8s. 6d. net.

THE extreme diversity among the algae has presented a compelling challenge to the development of classical phycology based primarily upon studies of morphology, life-history, taxonomy and ecology. A few algae have been selected for the physiological study of cellular processes such as photosynthesis and various aspects of membrane phenomena. Yet there have been few attempts to seek out and define those general or comparative aspects of physiology which characterize the group. The only two reviews of the subject, by L. R. Blinks¹ and J. Myers², did not appear until 1951 and were so limited in the field covered and divergent in point of view that they showed very little overlap. It is timely and appropriate that a more complete treatment of metabolism, the central core of algal physiology, should come from Dr. G. E. Fogg, an active member of a vigorously contributing group in University College, London.

The introductory chapter presents an abridged classification of algae and a classification of nutritional types which provides the basis of organization of the following chapters. Photosynthesis is presented as a necessarily brief survey of a large body of information. The attempt is directed toward exposition of the essential features of the process and the variations in terms of pigment participation and hydrogen donors observed among the algae. A chapter on chemotrophic assimilation provides a more complete synthesis of scattered observations and considers the spectrum of relationships between photosynthetic and oxidative assimilation of carbon. The topic of nitrogen assimilation includes consideration of nitrogen fixation in the blue-green algae and ammonia

and nitrate assimilation as observed principally in *Chlorella*. Amino-acid requirements now known for species of *Euglena* and *Chlamydomonas* are treated separately in a short chapter, together with the few known cases of vitamin requirements, under the title of heterotrophic assimilation. The carbohydrate, lipid and nitrogenous cell constituents are considered both as products of metabolism and as distinguishing biochemical characteristics of the various algal classes. A chapter on growth and metabolism is concerned with their inter-relationships. The thesis is set forth that, as a result of minimal excretion and versatile metabolism, changes in environmental conditions may give rise to a great range of variability in cellular composition in the simpler algae. A final four-page summary chapter presents the necessary apology for the limited sampling of algae on which generalizations must be based and reiterates some of the salient ideas of previous chapters in justification of algal metabolism as a distinct field of study.

Since the book will have impact upon future treatments of the subject, criticism should be made of the nutritional nomenclature upon which it is organized. The 1946 Cold Spring Harbor Symposium on Quantitative Biology proposed an elegant and precise classification of nutritional types of micro-organisms³. The nomenclature was later applied to the protozoa by A. Lwoff⁴ and now is applied to the algae by Dr. Fogg. Thus algae may be classified as phototrophs or as chemotrophs, depending upon whether the chief energy source is provided by photochemical or chemical reactions. Subclasses of photo- or chemo-lithotrophs or photo- or chemo-organotrophs are distinguished by their requirement for inorganic or organic exogenous substances. The classical terms 'autotrophy' and 'heterotrophy' are relegated to what is now a minor distinction based upon ability to synthesize essential metabolites. However precise the classification and however logical it may have appeared in 1946, there are now arguments against its continued use. It is cumbersome in terminology. It has had only limited acceptance in the field of microbiology for which it was designed. It does not necessarily group together organisms most closely related metabolically, and its separation into different groups implies far more profound differences than actually may occur. For purposes of discussion of metabolism of the algae, the classification is not a necessity, and at several points it leads to awkwardness of organization. Question is raised as to the desirability of its continued use.

The book is broader in its scope than a review. At the same time, its small size precludes the detailed treatment of data and the criticism and speculation which might be expected of a more exhaustive treatise. It is not directed toward the specialist in the field. It will orient but will not critically instruct the student who desires to work in the field. It serves well the stated purpose of bringing together the scattered literature "into a general account of the subject which will be of interest to students of botany, microbiology, and biochemistry".

AIRBORNE MAGNETIC SURVEYS

ON November 27 the Royal Astronomical Society held a Geophysical Discussion, with the Astronomer Royal, Sir Harold Spencer Jones, in the chair, at which the post-war development of a method of carrying out magnetic surveys from the air was reviewed. So far, experience has been mainly confined to measurements of the variation of the total intensity of the geomagnetic field; but experiments with apparatus for measuring three components of the geomagnetic field are in progress in the United States, Canada and Great Britain.

Mr. J. Squires, of the Research Laboratories of Elliott Brothers (London), Ltd., described the 'fluxgate' measuring element, which consists of a high-permeability core surrounded by an a.c. energizing winding able to drive it into saturation. Since saturation occurs twice per cycle, an output signal composed of even harmonics of the drive frequency is generated, predominantly second harmonic when the core is only just saturated but containing up to the fortieth harmonic when driven well beyond saturation. In either case the presence of an external field affects the output which, after rectification, may be used for indicating the intensity of the field component along the axis and its sense. Mr. Squires gave details of the design and operation of fluxgate instruments, the sensitivities of which, under laboratory conditions, are 10–12 $\mu\text{V./}\gamma$ and 35–40 $\mu\text{V./}\gamma$ for the second harmonic and peak types, respectively. Corresponding noise-levels are 0.03 γ and 0.1 γ .

When used in aircraft, the measuring element is aligned along the earth's field by two other fluxgates mounted mutually perpendicular to it, the whole orientated by servo-mechanisms which maintain the two latter elements in zero-field conditions. In order to measure very small changes in fields, it is necessary to 'back-off' most of the main field, and this may be done by an auxiliary winding on the core fed from a temperature-stabilized battery. Drifts of less than 3 γ per hour are attainable. The fluxgate measuring-head may be either towed from, or mounted in a suitable part of, the survey aircraft. In the latter case, compensation for the aircraft's own field is necessary and may be achieved with small permanent magnets or strips of high-permeability material. 'Noise-level' after compensation is usually 1–2 γ . Mr. Squires mentioned that another form of measuring element, dependent on the change in a.c. resistance of a high-permeability wire when subjected to a magnetic field, might have applications in airborne survey work.

Mr. A. B. Malone, of the Anglo-Iranian Oil Co., Ltd., stated that the oil industry is interested in outlining deep sedimentary basins, where sufficient sediments might exist to permit oil accumulation. He thought that there is a good deal of over-optimism in the United States as to the ability of the airborne magnetometer to define depths to the crystalline basement and even to outline structure in the overlying sediments. From the nature of magnetic data, there can be no such certainty of interpretation. Depth calculations can be of two kinds. If the field is continued downwards until the anomalies become impossibly great, or if the magnetic anomalies are assumed to arise from 'point' sources, maximum depths can be assigned. Alternatively, one can assume the form of the causative body and calculate

depths to the body on that assumption. It is this latter method which has proved so successful in America. The anomalies are assumed to arise from large rectangular blocks having a different susceptibility from the surrounding basement rocks. The walls of the block are assumed to be vertical and extend downwards to great depths. It seems unlikely that the basement could everywhere be imagined to be of this nature; and, in fact, total magnetic intensity maps show that over large areas of the world it is not, as the anomalies are small in lateral extent and very irregular in pattern. When the depth of the basement increases, the anomalies merge into one another to produce finally a smooth picture with no anomalies of any magnitude. This is in marked contrast to the large regular anomalies found in the Bahamas and on the American continent over sedimentary strata exceeding 20,000 ft. in thickness.

On depth calculations in general, Mr. Malone said that the ordinary methods of Vacquier¹ would be of doubtful utility in such an area, as it is obvious that, with increasing depth to the basement, the anomaly pattern becomes smoother as the sharp anomalies merge into one another. One method, which appears to be useful in certain areas, is to select a part of the total intensity map where basement depths are known or could be estimated, and measure the average 'sharpness' of the anomalies over that part of the map. The total intensity map of this area is then extrapolated upwards, and the mean sharpness again measured at various heights. This enables the sharpness criterion to be related to depth, and the depths to basement over the whole area of the map can then be roughly estimated. In order that isolated values of the sharpness should not be given undue weight, some smoothing of the final map may be desirable. In areas such as the Bahamas, Mr. Malone thought that the anomaly pattern is such that Vacquier's methods would be applicable, although this has not been examined. This area was surveyed before the publication of Vacquier's book, and a different method was used. Here the anomalies were supposed to arise from truncated cones, and magnetic fields for a series of such cones were calculated and compared with the observed anomalies.

Mr. H. F. Finch, of the Royal Greenwich Observatory, referred to some observations recently made in America, where an airborne magnetometer has been employed to measure absolute intensity and direction of the magnetic field. From these measurements it is possible to calculate the values of the other elements. The results obtained appear, in general, to be good within $\frac{1}{2}^\circ$ in declination, and to within 200 γ in the horizontal and vertical components of the earth's magnetic field. Mr. Finch has been able to confirm this order of accuracy from a comparison of some of the airborne results, corrected for the effect of altitude, with land observations made in the same regions. The general pattern of the field, as given by the airborne observations, is also in good agreement with that reduced synthetically from the results of a spherical harmonic analysis made at the Royal Greenwich Observatory in the course of preparing the Admiralty Magnetic Charts for the epoch 1955.0.

Mr. P. A. Rankin, of Hunting Geophysics, Ltd., London, described the execution of an aerial magnetic survey. His organization used a Canco flying boat with the magnetometer head in a fixed position

under the tail. Latterly, a Percival Prince aircraft has been converted; the magnetometer head is fixed in the tail and is a universal one which can be used in any latitude, for low or high magnetic dip. The positioning is done by a 35-mm. cine camera, which exposes film at such intervals that the whole of the ground beneath the aircraft is recorded, the magnetometer record being marked at each film exposure. Generally, where the object is to outline geological bodies which lie close to the surface of the ground, the spacing of the magnetic profiles is of the order of $\frac{1}{2}$ mile and the flights are made at a height of 500 ft. above ground. However, where the magnetic material is deeper, as in the case of mapping the basement underlying oil areas, the spacing can be 1, 2 or 4 miles and the height can be a constant at 1,500–2,000 ft. above sea-level. The technique of magnetic control is to fly a series of lines, called control lines, around a network of fixed magnetic values, which act as datum values for the readings on the flight lines themselves. Where there are areas of low magnetic relief, this method is practical; where, however, the area is magnetically disturbed, it may only be possible to use selected points instead of lines. Whichever method is used, the aircraft flies over these points or over a series of points (called 'loop points') at least twice within, say, ten minutes. This allows the diurnal drift of the field over that period to be calculated. It is, of course, assumed that the daily variation is linear for that time period. A stationary magnetometer of the fluxgate type is run at the flying base so that during a magnetic storm flying can be stopped. Esterline-Angus curvilinear tape 5 in. wide was the early type of record used; the Leeds-Northrup tape, rectilinear 10 in. wide, has latterly been used, allowing for an easier reduction of data.

Next, Mr. Rankin described the reduction of the data obtained to produce total-intensity maps. The control network values must be determined, errors of closure around the network distributed and final values marked on the control lines, as plotted on the map. Values at intersections of control and flight lines are then determined, and thus values along the flight lines are determined and marked on the map and the contours finally sketched in. Mr. Rankin then illustrated how simple geological structures appear on aerial magnetometer maps (Figs. 1 and 2). Fig. 1 shows a strongly magnetic gabbro plug outlined on an airborne magnetometer map at 500 ft. altitude. The direction of plunge, known from

Fig. 1

geological work, can be interpreted from the magnetic profile. Fig. 2 shows a sharp anomaly produced by a sill-like body of serpentinized peridotite. The shoulder on the north-west side of the anomaly is caused by a belt of volcanic strata. The asymmetry of the profile is related to the south-west dip of the serpentine.

Dr. S. K. Runcorn, of the Department of Geodesy and Geophysics, University of Cambridge, pointed out that magnetic surveys are the one type of airborne geophysical survey likely to be available for a long time to come and would be used extensively in hitherto unexplored areas of the world. Their success in picking out ore bodies has been striking, and ho

Fig. 2

referred to the discovery by the Aero Service Corporation of Philadelphia, using such surveys, of an extensive iron-ore body beneath the property of the Bethlehem Steel Co. at Morgantown, Pennsylvania. This body lies under 1,500 ft. of limestone, and previous extensive geological and ground survey failed to locate it; it is apparently dangerous to under-estimate the economic potentialities of this new method of exploration.

Apart from the well-marked magnetic anomalies of such ore concentrations, one has mainly to consider the anomalies caused by the surface contours and polarization variations of the basement rocks. Usually highly contorted and of igneous or plutonic origin, these rocks will have high intensities of magnetization (approximately 10^{-3} gauss) due to a high content, a few per cent, of iron oxides and due to the thermoremanent magnetization acquired on cooling after deep burial or metamorphism or from a magma. Apparently such thermoremanent magnetization is greater than the induced magnetization in the earth's present magnetic field, and as there is now much evidence that the direction of the field, both in declination and dip, has varied considerably over geological times, the validity of the interpretation of magnetic anomalies in terms of variations in intensity, but not in direction, of the polarization of the basement rocks is in some doubt. Some of the ferromagnetic constituents of rocks are unstable magnetically, and the polarization of rock samples containing these oxides will rotate into the direction of the field in which they are placed. Such effects may be more general at the higher temperatures at depth, and over long times, and the assumption of a basement magnetized along the present direction of the geomagnetic field may in the end be justified. The sedimentary stratum covering the contorted basement rocks is often flat-lying and normally has a low intensity of magnetization (say, 10^{-6} gauss) owing partly to the segregation of the heavy minerals due to erosion and deposition and the absence of effective processes of magnetization as in the case of igneous rocks.

Scientifically, airborne magnetic surveys are of enormous interest in view of the rudimentary nature of our knowledge of the structure at depth and especially the differences between the oceanic and continental areas. It has been pointed out by Deel² that there are apparently no anomalies of intermediate extent between those which can plausibly be attributed to the current systems of the main

geomagnetic field in the depths of the mantle and core and those anomalies the origin of which lies in the ferromagnetism of the crust. Consequently, the depth to the Curie-point isotherm where rocks cease to have ferromagnetic properties bears a relationship to the width of the magnetic anomalies observed at the surface. Recently, the discussion of the temperature distribution and radioactivity heat generation in the earth's crust has been renewed by the discovery that the geothermal gradient in the ocean bottoms seems to be nearly the same as that in the continents, despite the absence of a granitic layer of relatively high radioactive

content.¹ Consequently, the depth of the Curie-point isotherm under the oceans and the continents may be very different, and a comparison of the width of the magnetic anomalies obtained over oceanic and continental regions, such as could be easily obtained by the total-intensity aerial magnetometer, would be of great interest.

Dr. Runoorn concluded by suggesting that an aerial magnetic survey of the British Isles is much needed for comparison with the wealth of geological and gravitational data available. S. K. RUNOORN

THE R. W. PAUL INSTRUMENT FUND

UNDER the will of Mr. R. W. Paul, who died in March 1943, the R. W. Paul Instrument Fund was established, and in 1945 a committee was set up composed of three representatives of the Royal Society and one each of the Physical Society, the Institute of Physics and the Institution of Electrical Engineers. This committee is empowered by the terms of the Trust to receive applications from British subjects who are research workers in Great Britain for grants for the design, construction and maintenance of novel, unusual or much-improved types of physical instruments and apparatus for investigations in pure or applied physical science. These grants may be made for or towards the provision of equipment, building facilities or financial or other aid, in such a manner as the committee may determine; but grants from the Fund may not be used to relieve expenditure in any establishment controlled by the Government or to relieve any university or other educational establishment of its normal financial obligations.

Since its inception the committee has voted £56,350 in respect of some eighteen instruments, some of which are mentioned below.

The mechanical forces exerted by electromagnetic fields have been applied to the measurement of microwave power in work now in progress by Prof. H. M. Barlow and Dr. A. L. Cullen in the Electrical Engineering Department, University College, London. A practical torque-operated wattmeter for the absolute measurement of microwave power in the

range 10–60 W. at 3 cm. wave-length with an accuracy of about 1 per cent has been devised by Dr. Cullen; its calibration involves measurements of mass, length and time only. Efforts are now being made to use electrical and mechanical resonance for the measurement of smaller powers at shorter wave-lengths.

A vibration gravimeter has been constructed by Mr. B. C. Browne and Mr. R. L. G. Gilbert, Department of Geodesy and Geophysics, in the University of Cambridge. The gravimeter consists essentially of a vertical filament tensioned by the weight of a constant mass. The natural frequency of transverse vibrations of the filament depends on the tension and hence on the local value of gravity. This frequency is measured by comparison with a crystal-controlled frequency standard. Even if the frequency fluctuates, the average value can be determined with an accuracy better than one part in a million. The gravimeter can therefore be used on an unsteady support. It has been used to measure gravity in a submerged submarine¹ and has now been adapted for remote operation for investigating the vertical gravity gradient in a borehole².

In Lord Charwell's laboratory at Oxford two spectrometers have been developed. One, a photoproton spectrometer, measures the energy of gamma-rays above 2.2 MeV. Photoprotons are produced by gamma-rays in a deuterium-filled (5 atmospheres pressure) ionization chamber. After amplification their pulse-height spectrum is analysed by a 25-channel kick-sorter. Mono-energetic gamma-radiation will produce a single photoproton peak, and not a continuous pulse-height distribution. It is possible to detect very weak radiation in the presence of a strong background of radiation of lower energy. In this way a new line in the spectrum of sodium-24 at 3.7 MeV. (intensity 1/2,500) was found³. The energy of a photoproton depends on the angle of emission with respect to the beam. This makes it possible to determine the angular distribution by analysing the shape of the pulse-height, which is of theoretical interest. Measurements have been made for gamma-energies of 2.76, 2.62, 2.51 MeV.⁴. The techniques and equipment developed for this instrument are also used in connexion with the investigation of gamma-rays with a Compton spectrometer and a pair spectrometer^{5,6}.

The energy of fast neutrons is usually determined from the spectrum of recoil protons (hydrogen-filled ionization chambers, organic scintillating crystals, photographic plates). These methods have the common disadvantage of poor resolution and difficulty in the interpretation of results. In the fast-neutron spectrometer developed, only those recoil protons are selected which have suffered a head-on collision. This is achieved by measuring coincidences between pulses produced by recoil protons due to the primary neutrons in a stilbene crystal and pulses produced in a sodium iodide crystal surrounded by a layer of silver (1 cm.) by capture gamma-rays from the scattered neutrons. By means of a time delay (3×10^{-8} sec.) neutrons which have lost at least 99 per cent of their energy in the stilbene are selected. The instrument gives a peak for mono-energetic neutrons, not a continuous spectrum. It has an energy resolution of 5 per cent at 2.5 MeV. This instrument has been adapted for the measurement of the energies of low-lying levels of nuclei excited by the inelastic scattering of fast neutrons⁷.

In the analysis of a crystal structure it is necessary to measure hundreds and even thousands of integrated X-ray diffraction intensities from the crystals. Much of this is done by eye estimation; but higher accuracy of experimental measurement can be achieved by photometry of photographs. Photometry of ordinary X-ray photographs, however, is exceedingly tedious because no really satisfactory integrating photometer has yet been produced. The alternative, proposed by Wiebenga and Smits (1950), is to cause the integration to be done by giving the actual X-ray camera a scanning motion during exposure, so that a single photometric measurement in the centre of the resulting spot gives the integrated intensity directly. Prof. E. G. Cox and Mr. D. S. Beard, of the University of Leeds, have designed an integrating mechanism which can be fitted to a Weissenberg goniometer of British manufacture and which gives results of high accuracy. Although the mechanism is costly to make, it eliminates the need for an even more costly photometer, since a very simple photometer suffices for the measurements required; and although it increases the time needed for taking X-ray photographs, it reduces very greatly the time required for their measurement.

The purpose of an interference microscope constructed by Dr. D. Gabor, of the Electrical Engineering Department, Imperial College of Science and Technology, London, is to obtain a complete record of microscopic objects in two photographs; moreover, these records are obtained with a small fraction of the illumination required in ordinary instruments, by making use of an amplification principle. It is hoped that ultimately this may be used in the microscopy of light-sensitive organic structures. In the new microscope a coherent light beam is split into two unequal parts. The smaller part passes through the object, which is in one branch of an interferometer, while the larger part, the 'coherent background', passes through the other. Each beam is split into two, and a quarter-wave phase shift is produced between the two background-beams. These are then paired with the two image-carrying beams, and produce two photographs on a plate, side by side. Whether the object is focused on the plate or not, these two photographs contain a complete record of the image wave. The densities in corresponding points are proportional to two amplitude components, in quadrature with one another. Reconstruction is carried out in the same apparatus by illuminating the photograph with two uniform waves, again in quadrature to one another. The reconstructed beam can be explored in depth, in dark field, bright field, amplitude contrast or phase contrast, just as if one had the original object under investigation.

Prof. A. V. Hill, with Dr. D. K. Hill and Dr. D. R. Wilkie, has been working in University College, London, on new types of galvanometers and radiometers and on apparatus for studying material at high pressure. The problem of constructing galvanometers of short period (for example, 5 msec.) with sufficient sensitivity has been solved by employing photoelectric amplification of the deflection. The short period requires a very light moving coil, and the high magnification demands extreme freedom from extraneous disturbance. The latter is achieved by (a) symmetry of the moving system, involving very accurate construction, (b) using alternate springs and masses in the mounting. The magnified deflection is displayed on a cathode ray tube. Several such galvanometers have now been in use for years,

at sensitivities normally obtained with instruments of 1-2 sec. period.

Two chambers have been constructed for studying the effects of high pressure (up to 1,000 atmospheres) on muscular contraction. These are very satisfactory, the pressure being easily produced. The rapid changes occurring after stimulation must be recorded externally. Difficulties are provided by (a) the small size of the pressure chamber, (b) having to fill it with salt solution, and (c) electric leaks. Moreover, no existing electro-mechanical transducer is suitable for high pressures under these conditions, and new techniques must be devised. These difficulties are being overcome and preliminary results have revealed various interesting new effects.

Dr. H. H. Hopkins, of the Technical Optics Section of the Physics Department, Imperial College of Science and Technology, London, has designed a static scanning fibrescope the aim of which is to provide a flexible unit capable of transporting optical images along its length. Upwards of 50,000 fibres of glass, of a type such as the boro-silicate crowns giving high transmission, are aligned in a regularly arrayed bundle, some 0.20 in. square and 30 in. long. An optical image formed on one end-face of the bundle is now transferred to the other end, since the light falling on any one fibre is 'trapped' in that fibre because of total internal reflexion. A transmission of 25-50 per cent is expected in the final instrument; and already, even using coarser fibres, detail 0.005 in. in size can be resolved and the image is of good contrast. A particular use in view for the fibrescope is gastroscopy and similar medical techniques.

A small diffraction-grating ruling engine is being built by Dr. A. H. Holbourn and Prof. R. V. Jones, of the University of Aberdeen, to test the possibility of controlling the line spacing by direct reference to a light-wave interference pattern. This would eliminate the errors arising from the use of a screw. The pilot model is intended to produce concave gratings 8 cm. $\times$ 5 cm.; the absence of periodic errors should give ghost-free spectra. The technique of using light waves directly for mechanical control, which has been developed specially for this ruling engine, may have other applications.

Dr. O. Klemperer, of the Physics Department, Imperial College of Science and Technology, London, has constructed an electron spectrometer of high resolving power which will be useful whenever fine structures in any electron spectrum have to be investigated. The instrument uses a short magnetic deflexion field of very small aberration for the dispersion of the electron spectrum. A magnetic lens forms an intermediate image of the source closely in front of the deflexion field, while the deflexion field, acting as an astigmatic lens, projects the final image of the source on the collector slot. The spectrometer can be used for beta-rays of 10⁴ eV. For weak beta-sources, the greatest possible collecting power is required, and for this purpose a four-pole magnet has been used. This is inserted between the deflexion field and collector slot in order to counteract the astigmatism of the deflexion field and so to shorten the line image down to the length of the collector slot. A resolving power of about 1,000 has been obtained with a collecting power of about 1/1,000. The spectrometer is being used at the moment for an investigation on quantum losses of electron energy at inelastic collisions in solids. Electrons of only 5-10 keV. are transmitted through thin films, and

discrete losses of 10-20 eV. are measured. Here an increased resolving power is obtained by decelerating the rays down to 800 eV. before they enter the deflexion field. In this way the resolution has been increased sufficiently to locate the lines in a spectrum of a 10-keV. beam within a fraction of a volt.

A team of workers under Prof. N. F. Mott in the University of Bristol is developing a meniscus Schmidt meteor camera—a camera of wide aperture and short focal length, with a large field. After experience obtained with a small camera made from plate glass (aperture 6.5 in., $F/0.7$ (nominal)), the construction of a small-scale pilot model was commenced and is now nearing completion and should be ready for use this March. This will have a focal ratio of $F/0.63$ (nominal) or $F/0.78$ (effective), with a field of 56°. The stop diameter is 8.6 in. (focal length 5.4 in.) and mirror diameter 17 in. The full-scale model will have a mirror of diameter 28 in. The lens and mirror systems of these cameras have been designed independently; it has not been possible to compare them with the American models, full details not being available. The shutter system is original and avoids drilling holes in the mirrors through which to pass the rotating axle; the use of curved photographic plates is also unique to the Bristol instrument, the coating of these plates having been already accomplished successfully. The camera will be used in conjunction with the radar equipment at Jodrell Bank, Cheshire, to photograph meteors; a rotating shutter enables velocities to be measured. Information such as luminosity, velocity and decelerations will be obtained. From these observations, physical conditions in the upper atmosphere and collisions between molecules of high energy can be investigated.

A conventional spectrometer, in which the detector scans the elements of the spectrum one at a time, is inefficient in that only one element out of the whole spectrum is actually being observed at any moment. In the multichannel spectrometer being constructed by Prof. R. O. Redman at the Observatories, University of Cambridge, this loss is avoided by applying modulation patterns to the intensities of the spectral elements in such a way that they may act on a single detector simultaneously throughout the whole time of observation and yet be separable at the output of the detector. In the instrument under construction, the modulation is effected in a two-beam interferometer without the use of any dispersing system such as a prism or grating. The multichannel spectrometer should be specially valuable for faint radiation sources in the infra-red, and if successful will ultimately be applied to infra-red stellar spectra.

Information about application for grants from the R. W. Paul Instrument Fund can be obtained from the Assistant Secretary, Royal Society, Burlington House, Piccadilly, London, W.1.

THE ADULT FEMALE LOWER JAW FROM MAKAPANSGAT

By Prof. RAYMOND A. DART

University of the Witwatersrand

IN Makapansgat Valley near Potgietersrus in the Central Transvaal on July 29, 1953, Mr. Alun R. Hughes, senior technician in the Department of Anatomy, University of the Witwatersrand, recovered from the Limeworks dump, which has previously yielded cranial and pelvic remains of adult, adolescent and infantile specimens of *Australopithecus prometheus*, the major portion of an undistorted adult and probably female mandible.

The accompanying photograph (Fig. 1) illustrates first the specimen itself and secondly its appearance (below) in comparison with (above) the infantile *A. africanus* mandible from Taungs (Dart, *Nature*, 1925) and (centre) the adolescent *A. prometheus* mandible from Makapansgat (Dart, *Amer. J. Phys. Anthropol.*, 1948).

These three australopithecine mandibles, collected during the past thirty years, fortunately are all undistorted. Each preserves virtually the entire dentition at the crucial growth stage it represents. Simultaneously, they display collectively the anatom-

Fig. 2. Outlines of jaws of: *Australopithecus prometheus*, —; *Paranthropus crassidens*, ----; Heidelberg man, —. $\times 3/5$ natural size

ical details of the lower jaw and its dentition in a complete and unqualified fashion. The growth process as well as the form of the australopithecine mandible, both subsequent to and preceding the establishment of the milk dentition, was indistinguishable from that which occurs in mankind.

The new adult jaw is unique at the moment, because it is the only one so far to have preserved the entire incisor-canine-premolar-molar dental arcade without warping, compression or dental dislocation. Although the lower third of the symphyseal region was blasted away, little of the essential anatomy of the jaw is lost. From the adult occipital and craniofacial, and the adolescent mandibular fragments of *A. prometheus* recovered in 1947 and 1948, a provisional reconstruction was made available in 1950 to all museums and anthropologists at cost, through the generosity of the American Institute of Human Paleontology and the Wenner-Gren Foundation which assisted in founding it. It is gratifying to record that scarcely 2 mm. alteration is necessary in the dimensions of the profile, or norma lateralis, of that reconstruction for its mandibular contour to correspond with that of the specimen now under discussion.

The most remarkable feature of this, the most nearly human of all known South African man-ape dentitions, is that the dental arcade can be superimposed tooth for tooth upon the dental arcade of Peking man. The dental length in the promethean man-ape is actually less. The chord of the dental arcade from the mesial border of the medial incisor to the distal border of the third molar measures 75 mm. in Peking man and only 73 mm. in the Makapansgat man-ape. The bicanine width in the *Sinanthropus* male is 37.5 mm. and in the *A. prometheus* female 35.5 mm. The width of the second molar in the primitive man from China is 14.0 mm. and in the proto-human individual from the Transvaal 14.5 mm. Actually, the Makapansgat premolar-molar series of teeth is slightly larger, while the incisor-canine series is slightly smaller, than the corresponding Peking series.

The Makapansgat mandible is shorter and more robust than that of Peking man, but definitely much shorter and less robust than those of its near South African relatives *Plesianthropus* and *Paranthropus*,

Fig. 1. Upper: infant *Australopithecus africanus* (Taungs). Middle: adolescent *Australopithecus prometheus* (Makapansgat). Lower: adult female *Australopithecus prometheus* (Makapansgat). $\times 3/5$

showing the wide range of potential variation at the australopithecine phase of human evolution. The really astonishing fact, however, is that this mandible is considerably smaller (see Fig. 2) than the mandible of Heidelberg man. There is no satisfactory means of distinguishing the lower jaw or its teeth in *Australopithecus prometheus* from those of some of the primitive human beings already known to science.

In their jaws and dentitions as in their postural uprightness and predaceous habits, the South African man-apes were human. There is no known criterion whereby the Australopithecines can be excluded from the zoological status of an intermediate family of creatures having the brains of apes and the bodies and nutritional habits of mankind.

OBITUARIES

Prof. Robert A. Millikan

THE distinguished American physicist, Dr. Robert A. Millikan, died on December 19, after an illness of several months, at his home in Pasadena, California; he was eighty-five years old. Dr. Millikan was born in Morrison, Illinois, on March 22, 1868, the second of six children. His father, Silas Franklin Millikan, was a Congregational minister. Before her marriage, his mother, then Mary Jane Andrews, was Dean of Women of Olivet College, Olivet, Michigan.

Millikan attended Oberlin College at Oberlin, Ohio, where he received his A.B. degree in 1891 and his A.M. degree in 1893. He held a research fellowship at Columbia University during 1893-95, when he received from that institution his Ph.D. degree. The following year he continued his study and research at Berlin and Göttingen.

In the autumn of 1896 he was appointed an assistant in the Physics Department in the University of Chicago. In his twenty-five years at that University Dr. Millikan progressed through the academic ranks to become one of that institution's most outstanding professors. In 1921 he went to Pasadena, California, as the chairman of the Executive Council of the California Institute of Technology and also served as director of the Norman Bridge Laboratory of Physics. He retired from these positions in 1945, but continued his active participation as a vice-president of the Board of Trustees of the Institute and as a research worker in the Norman Bridge Laboratory.

The Nobel Prize in Physics for 1923 was awarded to Dr. Millikan for his precision evaluation of the electronic charge e and of Planck's constant of action. The Hughes Medal of the Royal Society, the Comstock Medal of the U.S. National Academy of Sciences and many awards, honorary degrees and academy memberships have clearly shown the world-wide recognition and distinction that he deserved and received. His most important contributions were in the measurement of the charge of the electron, the photoelectric determination of Planck's constant, the bridging of the gap between the ultra-violet and X-radiation, and his explorations of cosmic radiation. In addition to these major fields of research, Millikan contributed substantially to many other fields. With unusual physical stamina and energy, he was able to spend more than sixty years in active participation in physical research. It was characteristic of most of his research that many hours of painstaking observation and analysis were required for the problems

undertaken. Measurements made with great care were repeated many times to obtain from his equipment the greatest accuracy. Careful analysis of the data yielded experimental facts that enabled him to refine both his equipment and his analysis of the data to give results in physical measurements of remarkable precision. The great variety of fields in which he made important contributions emphasizes his unusual ability in recognizing and developing critical and important areas for research.

Dr. Millikan's contributions to education in the United States brought him many honours and recognition as a great educator. As a college student he taught physics in a preparatory school and found the text-books available unsatisfactory. His first years at the University of Chicago were partially occupied with a programme of writing texts for preparatory school and first-year university courses. His text-books, widely used throughout America for half a century, have been important influences in scientific education. In the creation and development of the University of Chicago he was a strong advocate of the concept that departments should be composed of a group of independent scholars, one of whom, for administrative purposes, is chosen as a chairman. In the California Institute of Technology he developed an outstanding engineering school combined with a very distinguished and able graduate school in basic science. The thousands of graduates of this unique institution are now a very important influence in American technology. The development of the National Research Council was due, in a large measure, to the efforts of Millikan. The post-doctoral National Research fellowships provided a substantial group of able research scientists who were the leaders of the National Defense Research Council and of its projects in the Second World War. Millikan was, himself, an active worker in the military forces in the First World War. In the second his Institute, with many staff members on leave to military and scientific research, carried on a large training programme for military students, and at the same time developed and produced important military weapons.

Millikan began his career at the time of a great revolution in physics. He witnessed and participated in the initial discussions regarding the nature of cathode rays, X-rays and radioactivity. The radical ideas of the quantum theory and of the theory of relativity were supported enthusiastically by the young Millikan.

The period following the First World War was a transition period for the world, and also for Dr. Millikan. The practical applications of scientific discoveries had led to such radical changes in transportation, in communication, and in industrial and chemical production that the century was marked as the scientific era. The homage paid to science for the part it has played in changing our concepts of matter and life brought on an attack from those who saw a conflict between science and religion (for example, the 'monkey trials' in Tennessee). With Millikan's move to the California Institute of Technology he became the spokesman for those who believed that science was neither materialistic nor irreligious. In taking this conservative position, Millikan received great acclaim from many religious groups. In assessing his own success, Millikan gave credit to Divine guidance or a "good fairy" for the opportunities that came to him.

His wife, Greta Blanchard Millikan, died two months before his own death. His eldest son, Clark

B. Millikan, is professor of aeronautics at the California Institute of Technology. His second son, Glenn A. Millikan, who was professor of physiology at Vanderbilt University, was killed in a mountaineering accident in 1947. Glenn Millikan's wife was Claire Mallory, daughter of George Leigh Mallory, the Mount Everest climber. His youngest son, Max F. Millikan, is professor of economics in the Massachusetts Institute of Technology.

ROBERT B. BRODSKY

Prof. Oldřich Tomíček

PROF. O. TOMÍČEK's death, which occurred after a short illness on October 21 a few days after his sixty-second birthday, is a heavy blow to Czechoslovak analytical chemistry, for during the past twenty-five years he has been the leading analyst and pharmacist at the Charles University. He was born in Prague on October 10, 1891, where his father was a pharmacist, and early showed his scientific ability in publications with Prof. B. Brauner. Thus young Tomíček was predestined to the study of pharmacy and reached the degree of *Pharmaciae Magister* shortly before the outbreak of the First World War, in which he had to serve in a military pharmacy in Innsbruck. It is significant of the zeal of the young scientist that he found an opportunity of approaching Prof. K. Bruner to pursue special work on indol derivatives in the laboratories of the University of Innsbruck. The end of war brought Tomíček back to Prague and gave him the chance to widen his scientific knowledge at the Charles University under the guidance of the inorganic chemist Prof. Štěpán Böhmi. Here he took the degree of Ph.D. in June 1920 and was appointed university assistant. The years 1923-24 Tomíček spent in Utrecht in the laboratory of Prof. Schoorl to acquire potentiometry. There started his friendship with the rising scientist, I. M. Kolthoff, which proved most influential for the further development of Tomíček's line of research and lasted—supported by frequent meetings of both men at various international gatherings—until Tomíček's death. The two friends worked out the foundations for the use of titanous chloride in potentiometric titrations.

Later on, as assistant professor of analytical chemistry in Prague, Tomíček worked on the potentiometric determination of cerium and started with his school a series of studies of volumetric determinations in strongly alkaline medium. His chief work in that direction was published in the *Journal of the American Chemical Society* during 1935, where he gave practical applications for the titrations of cobalt, manganese, bismuth, thallium and cerium, using amalgams for the reduction, and ferricyanide, hypochlorite or hypobromite for oxidation. In that year Tomíček was nominated full professor.

In 1943 he started to study potentiometric and polarometric titrations in non-aqueous solutions, chiefly in glacial acetic acid. This line of research required special attention from the theoretical aspect as regards the meaning of neutralizations and pH values. These discussions are therefore of high theoretical value and of fundamental interest, promising also possibilities of wide practical applications.

Prof. Tomíček was also held in high regard in pharmaceutical circles, being co-editor of the Czechoslovak "Pharmacopoeia" and revising the

analytical problems involved. He was expert also in forensic chemistry.

As a university teacher, Tomíček proved an excellent lecturer, devoted to his pupils. For them he wrote in Czech several valuable text-books on quantitative and volumetric analysis. Of his scientific monographs the best known and appreciated is "Chemical Indicators", which was translated into English (Butterworth, London, 1951). Besides this, Tomíček contributed at the international level to the "Handbuch der analytischen Chemie" (J. Springer, Berlin, 1944 and 1948) with accounts on ammonium, oxygen, sulphur, selenium and tellurium. In his own country, also, Prof. Tomíček was highly esteemed. For many years he was president of the Czechoslovak Chemical Society, of which he was made an honorary member, president of the Pharmaceutical Society and corresponding member of the Czechoslovak Academy of Science.

Tomíček was an extremely kindly man, always willing to help his numerous friends, colleagues and pupils, and inclined to overwork himself for unselfish reasons. His non-academic interests were mountaineering, motoring and skiing. Thus not only in scientific minds, but also in many hearts, Prof. Tomíček's death has left an open gap.

J. HRYBOVSKÝ

Dr. F. C. Minnett, C.I.E., M.B.E.

DR. F. C. MINNETT, director of the farm livestock research station of the Animal Health Trust, died on December 26 at the age of sixty-three.

Francis Colin Minnett was born on September 16, 1890, and was educated at King Edward's School, Bath, the Royal Veterinary College, London, and the Pasteur Institute, Paris. He qualified as a veterinary surgeon in 1911 and worked for the next three years in the pathology department of the Royal Veterinary College under Sir John MacFadyen. During 1914-24 Minnett was an officer in the Royal Army Veterinary Corps. He then became a research officer of the Ministry of Agriculture's veterinary laboratories until 1927, when he was appointed director of the Research Institute of Animal Pathology at the Royal Veterinary College; in 1932 he became professor of pathology. In 1939 Minnett went to India as director of the Imperial Veterinary Research Institute at Mukteswar. On the division of India he became commissioner for animal husbandry in Pakistan until 1949, when he joined the staff of the Animal Health Trust. At the request of the Foreign Office, he was soon seconded for two years as veterinary adviser to the Turkish Government.

Minnett was a prodigious worker, mainly upon bacteriological problems concerned with disease in animals. He was a strenuous bench worker throughout his life, although he never neglected—indeed he encouraged—the translation of laboratory work to the farm. His work was mainly concerned with diseases of cattle, and he studied in turn bovine tuberculosis, contagious bovine abortion, Johne's disease, foot and mouth disease and mastitis. He also investigated mastitis in sheep, blackquarter, anthrax, strangles in horses, mortality wastage among livestock in India, and the health of animals as affected by climatic conditions. In all, he published more than fifty papers in scientific journals.

Probably the main work which Minnett did was to focus attention on the serious loss in Great Britain occasioned by mastitis in cattle. He divided the

Streptococcus forms into three groups, and it was shown that his Group I coincided with *Str. agalactiae*, information which was already known in other countries. He and his colleagues were the first to point out the etiology of his Group II, which is known as *Str. dysgalactiae*. His Group III is now known as *Str. uberis*. Probably the best defence that Minett ever gave for the work which he and his colleagues did is in an article published in the *Journal of Hygiene*, 35, 504 (1935). This was in answer to an attempt by some medical bacteriologists to delve into a veterinary problem. His work also included the demonstration that certain human strains of *Streptococcus* could affect the udder of the cow, and

in turn that affected milk may cause an outbreak of human disease. He directed attention to the toxin production of *Staphylococci* of animal sources; these differ in some degree from the human pathogens. His work on John's disease was largely concerned with methods of isolation and types of media, in addition to collaborating with others in the diagnosis of the disease, particularly by Johnin.

Minett was a strenuous worker, who expected equal work from his junior colleagues; he appeared stern, but beneath an apparently hard exterior he was warm-hearted and full of fun. His early death is a great loss to British veterinary science.

W. R. WOOLDRIDGE

NEWS and VIEWS

Mr. Cecil Warburton: 100th Birthday

ON February 6, Mr. Cecil Warburton celebrated his hundredth birthday. Mr. Warburton entered Christ's College, Cambridge, in 1876. He became a demonstrator in the School of Agriculture and in the Department of Zoology in the University, and later he was a member of the Quick Laboratory which eventually grew into the Molteno Institute. Mr. Warburton has always had wide interests in general entomology and was for many years honorary zoologist to the Royal Horticultural Society (of which he was elected a life member at the age of ninety-six). He has published papers, etc., on spiders, and wrote the section on Arachnida in the "Cambridge Natural History" (Macmillan). Perhaps his best-known scientific work is on the ticks, in collaboration with the late Prof. G. H. F. Nuttall, which led to the production of the standard monograph on this economically important group of animals. For many years now, Mr. Warburton has been a living confutation of the gerontologists, for he has maintained in almost legendary degree his activity of body and of mind—at least he still plays bridge and chess (at which many years ago he represented the University of Cambridge), he is still a dangerous opponent at croquet, and solves *The Times* crossword puzzle each day. At the luncheon given in his honour on the eve of his birthday by his old College, he responded with a lively speech; he was also entertained at luncheon on his birthday by his colleagues at the Molteno Institute of Parasitology.

Geology at Belfast:

Prof. J. K. Charlesworth

ALTHOUGH The Queen's University in Belfast has an ancestry going back more than a hundred years, its chair of geology was founded only in 1921. The first occupant, Prof. J. K. Charlesworth, this year retires from the service of the University in the proud knowledge that the task of creating a department almost from its foundations is visibly fulfilled in the newly completed building that forms such an adornment to the University's post-war fabric—though it must be a source of keen regret to him that he has been able to occupy his new rooms for so short a time. After graduating at Leeds under P. F. Kendall, Prof. Charlesworth carried out research and obtained his doctorate at Breslau. He finally moved to Belfast from a senior lectureship at Manchester. His academic interests have been mainly in Pleistocene geology, especially in the history of the Ice Age in Britain; and his work has achieved world-

wide distinction for the manner in which he has elucidated late-Glacial changes and described the deposits of the Newer Drift in England and Wales, the recession of the ice in southern Scotland, and the intricacies of successive glaciations in Ireland. These contributions will shortly be rounded off with an elaborate analysis of the glaciation of the Scottish Highlands. In ancillary studies he has discussed the origin of the Irish Sea, and of the Irish fauna and flora. He has, however, never been narrowly content with specialist interests, but has used his position to popularize geology as a cultural subject, not least through his recently published book on the geological history of Ireland.

Dr. Alwyn Williams

PROF. CHARLESWORTH is to be succeeded by Dr. Alwyn Williams, a graduate and former Fellow of the University of Wales. While at Aberystwyth, he elucidated the complex structures of the classical Llandailo district, and began his studies in Lower Palaeozoic fossils. Thereafter he spent a year at the Sedgwick Museum, Cambridge, with Prof. W. B. R. King. In 1948 he went with a Commonwealth fellowship to the United States National Museum, Washington, where he worked with Dr. G. A. Cooper on fossil brachiopods, a group in which his main interest lies. Some of his researches on the morphology and taxonomy of protrematous forms have been the subjects of monographs issued by the American Geological Society. Since 1950 he has been lecturer in geology in the University of Glasgow, and has extended his work on Lower Palaeozoic rocks from Wales to the Southern Uplands. The wide outcrop of similar rocks running south and south-west from Belfast will give him further opportunities of applying his special knowledge when he takes up his appointment in Ireland.

Physics in the National Physical Laboratory:

Dr. Ezer Griffiths, O.B.E., F.R.S.

DR. EZER GRIFFITHS recently retired on his sixty-fifth birthday from his position as a senior principal scientific officer in the Physics Division of the National Physical Laboratory. Appointed shortly before the First World War, Dr. Griffiths had already done outstanding postgraduate research work at University College, Cardiff, which had culminated in two papers (*Phil. Trans. Roy. Soc.*) on the heat capacities of metals, written jointly with Principal E. H. Griffiths. These early interests have been maintained, for Dr. Griffiths has been in charge of the work on heat

during most of his time at the National Physical Laboratory. By his investigations into the thermal properties of materials and contributions to the science of refrigeration, he has established an international reputation. Twice he went to the Antipodes in charge of scientific investigations: first to study the incidence of brownheart in apples during shipment from Australia, and later to make a survey of the transport of New Zealand lamb. Dr. Griffiths's scientific publications have included three books, "Methods of Measuring Temperature", "Pyrometers" and "Refrigeration Principles and Practice", and about a hundred papers, of which for a joint one dealing with the fundamentals of evaporation he was awarded the Moulton Medal of the Institution of Chemical Engineers. Dr. Griffiths has held offices in many scientific societies, and is still serving as president of the Institut International du Froid. He has been succeeded at the National Physical Laboratory by Dr. R. W. Powell, who has been a member of the Heat Section since 1924.

British Association Secretaryship: Sir George Allen, C.B.E.

SIR GEORGE ALLEN, formerly vice-chancellor of the University of Malaya, has been appointed secretary to the British Association for the Advancement of Science in succession to Mr. D. N. Lowe. Sir George was born in Donegal and educated at the Methodist College and The Queen's University, Belfast. At the University he graduated in medicine. After service with the R.A.M.C. in East Africa during 1917-20, he worked for six years as bacteriologist in the Medical Research Laboratory in Nairobi. He then returned to England for postgraduate work in pathology at Oxford and in London hospitals. In 1928 he was appointed bacteriologist in the Institute for Medical Research at Kuala Lumpur. Shortly afterwards he became principal of the King Edward VII College of Medicine in Singapore; he was also president of Raffles College in Singapore. He assisted the Commission on University Education in Malaya to prepare plans for the creation of a University by the fusion of these institutions, and was the natural choice as first vice-chancellor when the new University was established in 1949. In the three years of his vice-chancellorship Sir George Allen succeeded, with tact and administrative skill, in blending two independent institutions into a thriving entity which is now playing an increasingly important part in the life of South-East Asia. He brings to his new work in the British Association a scientific and medical background, an informed sympathy for experimental and field research and wide experience in education and administration.

Element 99

WITH the ever-increasing amount of effort being devoted to research in nuclear physics, it is perhaps no longer surprising to learn of the production of yet another artificial element—number 99 in the Periodic System (*The Times*, February 3, quoting a statement from the U.S. Atomic Energy Commission). It is well known that there are at least two routes by which new heavy elements may be formed, namely, by successive neutron capture in lighter elements, followed by beta-decay, and also by the nuclear interactions of 'heavy' ions such as $^{16}\text{O}^{++}$, $^{14}\text{N}^{++}$, $^{18}\text{O}^{++}$, accelerated in cyclotrons and used to bombard suitable targets. Both these methods may have been

employed; but only one mass assignment has been made, namely, $A = 247$. The nucleus 99^{247} is understood to decay by alpha-particle emission with a half-life of a few minutes. Although this achievement is not unexpected, it reflects the greatest credit on Prof. G. T. Seaborg, of Berkeley, California, and his collaborators. It will be interesting to learn what name the discoverers will propose for the element. The chemical properties may be predicted with some certainty on the basis of Seaborg's actinide hypothesis, and if such properties are in fact observed, one may refer to the element temporarily as eka-holmium. The rare earth holmium was named after Stockholm. One wonders whether the discoverers of element 99 can find a name for it, based on a place-name, which is anything like so euphonious.

Effect of Germanium on the Transformation of White to Grey Tin

THE (normally) slow transition of the white, tetragonal form of tin to the grey, cubic modification at 13.2°C . is well known, as is the fact that inoculation with the grey allotrope accelerates the transformation. It is now shown in a paper by R. R. Rogers and J. F. Fyde, entitled "Effect of Germanium on the Transformation of White to Grey Tin" (Canadian Department of Mines and Technical Surveys, Mines Branch, Technical Paper No. 5; pp. 11. Ottawa: Queen's Printer, 1953; 25 cents), that inoculation with germanium is similarly effective in producing the grey form, the tin and germanium being immersed in a strong aqueous solution of calcium chloride acidified with hydrochloric acid to pH 1.5 at a temperature of -80°C . Whereas the grey variety made its appearance only after 81 days with the 'pure' tin, 2 per cent of germanium caused its appearance after 4 days in the case of cast tin. It is noteworthy that in the case of hot-dipped tin coatings much longer periods are required than in the case of castings. The presence of germanium in the alloy, or in aqueous solution, has a corresponding accelerating effect. The presence of zinc in the tin results in a marked retardation of the change, the zinc-free alloy containing 2 per cent of germanium first showing the grey tin after 0.9 day at -40°C . as compared with 14 days when 2 per cent of zinc is also present. This effect of germanium is possibly one reason for the well-known difference of different varieties of tin in the rate of transformation, since some tin ores are known to contain small amounts of that element.

Fat from Fungi

IF fats are to be produced by the industrial utilization of moulds, cheap carbon sources such as cellulose waste and molasses must be considered. As sucrose is the major constituent of molasses, the first stage in the relevant investigations is to ascertain the behaviour of different moulds towards it. S. Murray, M. Woodbine and T. K. Walker (*J. Exp. Bot.*, 4, 11, 251; 1953) now report on the growth, development and fat formation of some forty-three strains of ten species of fungi when grown on different sucrose-containing media. The highest three yields of fat were given by *Penicillium janczonicum* van Beyma, *P. soppi* Zaleski and *Aspergillus nidulans* Eidam, in that order. The fat content on felt weight was maximal at 84.8 per cent with *P. soppi*, at 28.4 per cent with *Fusarium lini* (i), and at 25.8 per cent with *A. nidulans*; on sugar

utilized it was maximal at 11.4 per cent with *P. soppi*, at 7.9 per cent with *A. nidulans*, and at 5.6 per cent with *F. liri* (1). Other moulds are considered worthy of further trial.

Roman Gallery at the Grosvenor Museum, Chester

As part of a general reorganization of the Grosvenor Museum at Chester, a gallery previously devoted to art has been entirely ceased in modern style and now illustrates the Roman army. The collections at Chester are particularly rich in Roman material, and it was decided to illustrate the army, and in particular the legions, with special reference to the Chester fortress. The gallery is a long room of nearly 80 ft., and this has been broken up by creating three bays in cases of the shop-window type. This provides a singularly attractive display and provides very useful storage-room. Fluorescent tubes have been used both for the general and individual case lighting. The attention of the visitor is first attracted to a model of a soldier. Then follow panels dealing with a soldier's pay, Samian pottery, tools and equipment, building materials and other objects, leading to a large diorama of the Chester fortress showing its buildings, defences and its relationship to the local topography. The story continues, and to conclude is a final panel illustrating the defences of the Roman Empire.

Electron Microscopy: Conference in London

THE Joint Commission on Electron Microscopy of the International Council of Scientific Unions is sponsoring an international conference on electron microscopy, to be held in London during July 16-21. The detailed organization is in the hands of a committee comprising the members representing the Electron Microscopy Group of the Institute of Physics and members of the Commission resident in Great Britain. Sessions will be devoted to the following subjects: instruments and associated apparatus; electron optics; the attainment of very high resolution; reflexion methods; metallurgical applications; industrial and chemical applications; fixation and drying methods; microanatomy of cilia, etc.; fibrillar structures; structure of cell walls; internal structure of cells; bacteria; viruses; biological specimen techniques; metallurgical and general specimen techniques; and the effect of electron irradiation on matter. All workers interested in the field may attend the conference; they must register with the joint secretaries before March 1 (fee £2). Papers will be accepted for consideration, and authors should in the first instance make their offers to the secretary of the respective national society of electron microscopy, except that in North America they should send them to Prof. T. F. Anderson, 612 Maloney Building, School of Medicine, University of Pennsylvania, Philadelphia 4, and in countries where there is no national society they should send them to the secretary of the programme committee, Dr. V. E. Coslett, Cavendish Laboratory, Free School Lane, Cambridge. Notification of all papers should be made not later than March 1. The official languages of the conference will be English, French and German. An exhibition of electron microscopes, ancillary apparatus and books is being arranged. General correspondence relating to the conference should be addressed to the joint secretaries, Dr. C. E. Challice and Mr. F. W. Cuckow, c/o Institute of Physics, 47 Belgrave Square, London, S.W.1.

Third International Congress of Nutrition, Amsterdam

THE Third International Congress of Nutrition will be held in Amsterdam during September 13-18 under the auspices of the International Union of Nutritional Sciences. The programme will include sessions on the following topics: overnutrition and disease; nutrition and liver disease; parenteral nutrition; nutrition and the psyche; and non-nutrient foreign chemical substances in foods (intentional and unintentional additives). Invitations have already been sent by the local Dutch organizing committee to a number of proposed contributors; but nutrition workers in Britain, particularly members of the [British] Nutrition Society, who would like to participate in the discussions are invited to submit a title and a short synopsis (not exceeding two hundred words) of their proposed contribution for consideration. These should reach Dr. G. H. Bourne, honorary secretary of the Nutrition Society, Department of Histology, London Hospital Medical College, Turner Street, London, E.1, by February 28. Further information about the International Union of Nutritional Sciences can be obtained from the secretary-general, Dr. L. J. Harris, Dunn Nutritional Laboratory, University Field Laboratories, Milton Road, Cambridge.

International Union of Geodesy and Geophysics: General Assembly in Rome

THE International Union of Geodesy and Geophysics will be holding its tenth General Assembly in Rome during September 15-29. The constituent International Associations of Geodesy, Meteorology, Hydrology, Oceanography, Vulcanology, Terrestrial Magnetism and Electricity, and Seismology and the Physics of the Earth's Interior, will meet during the period. Delegates attending are nominated by the national adhering organizations of the Union. British scientists wishing to attend or to read or communicate papers may do so only if sponsored by the Royal Society on the recommendation of the British National Committee for Geodesy and Geophysics. Those wishing to submit papers for the scientific meetings should write to the Assistant Secretary of the Royal Society, Burlington House, London, W.1, not later than March 1.

Training of Biologists

THE Institute of Biology is arranging a meeting, to be held during April 21-22, to discuss the training of biologists. There will be four sessions: on the teaching of biology in schools to those intending to specialize; on undergraduate courses at universities; on biological work in technical colleges; and on postgraduate training. It is hoped that the meeting will attract teachers from schools, technical colleges and universities and representatives of employing bodies. Ample time will be allowed for discussion after the invited papers. A programme will be available early in March from the General Secretary, Institute of Biology, Tavistock House South, Tavistock Square, London, W.C.1.

Chemistry Meetings in Eastern Germany

THE Chemical Society of the Eastern Zone of Germany has recently issued details of the meetings it proposes to hold this year. The programme opens with a conference in Berlin during February 23-24 on the place of electricity in chemical industry and

ends at the close of the year with a celebration in Berlin of the 125th anniversary of the *Chemisches Zentralblatt*. Other meetings in Berlin will be one on the manufacture and use of plastics (April 13-14), which will partly be held also in Leipzig, one on dietetics and food chemistry (April 27-28) and another on artificial fertilizers (June 15-16). In Leipzig there will be a symposium on synthetic fibres during March 23-24, followed by the annual general meeting of the Society during October 20-23 and a discussion on the light metals during December 7-8. Finally, a meeting of chemistry *Doxents* will be held in Dresden during May 20-21. Further information regarding these events and the Society in general can be obtained from the Chemische Gesellschaft, Berlin NW7, Unter den Linden 68/70.

Physical Society: Spring Meeting In Dublin

THE spring meeting of the Physical Society will be held in the Department of Physics, University College, Dublin, during March 30-April 1, and will take the form of a symposium on "High-Energy Accelerators and Cosmic Rays", organized by Prof. T. E. Nevin. Speakers from the following institutions have been arranged: Atomic Energy Research Establishment, University of Birmingham, Brookhaven National Laboratory (United States), Dublin Institute for Advanced Studies, University of Manchester, Maynooth College, Queen's University, Belfast, and University College, Dublin. The meeting will be open to all. Application forms and further information can be obtained from the Physical Society, 1 Lowther Gardens, Prince Consort Road, London, S.W.7.

Announcements

PROF. A. C. FRAZER, professor of pharmacology and therapeutics in the University of Birmingham, has been elected an associate member of the Royal Flemish Academy of Sciences of Belgium.

LORD CHERWILL, professor of experimental philosophy in the University of Oxford, has been awarded the Messel Medal for 1954 of the Society of Chemical Industry. This Medal, which is the senior award of the Society, is presented once every two years to one who has secured meritorious distinction in science, literature, industry or public affairs, or who is prominently concerned in the welfare of the Society. Previous recipients include Sir Henry Tizard, Lord Bruce of Melbourne and Lord Waverley.

DR. N. H. MACKWORTH, director of the Medical Research Council Unit for Research in Applied Psychology, has been awarded the H. M. Vernon Prize of the National Institute of Industrial Psychology, for his work in directing and developing the studies carried out by his Unit in the field of human skilled performance, and for his personal contribution to a more scientific understanding of the effects of climatic conditions upon human behaviour. This is the first award of the Prize, which was founded by the Institute with a sum of money bequeathed by the late Dr. H. M. Vernon, an investigator of the Industrial Health Research Board and one of the original investigators of the Health of Munition Workers' Committee in 1915. The Prize is to be awarded every second year to the investigator who, being a British subject and under the age of forty-five years, has in the opinion of the Council of the Institute done the most valuable research work in the subject of industrial psychology and physiology.

THE Harrison Memorial Prize for 1953 has been awarded by the Chemical Society to Dr. Ronald James Gillespie, lecturer in chemistry in University College, London, for his work on the electrochemistry of strong-acid solvents published during the five years 1949-53. Dr. Gillespie is at present carrying out research on the dielectric properties of polar liquids at Brown University, U.S.A. The Harrison Prize was created in 1922 to commemorate the services of the late Colonel Edward Frank Harrison, formerly deputy controller of the Chemical Warfare Department, for the protection of the British Forces from poison gas during the First World War. It is awarded to the British chemist, less than thirty years of age, who, in the opinion of the Selection Committee, has during the previous five years conducted the most meritorious and promising original investigations in chemistry and published the results.

PROF. JOHN YUDKIN, professor of physiology in Queen Elizabeth College, London, has been appointed to the University chair of nutrition tenable at that College. The title of professor of civil engineering in the University of London has been conferred on Mr. J. W. H. King, in respect of the post held by him at Queen Mary College, London. The title of reader in photogrammetry in the University of London has been conferred on Dr. E. A. Miakin, in respect of the post held by him at University College, London.

THE Institution of Chemical Engineers is holding a symposium on "Gas Absorption" during April 5-7 in the University of Birmingham. The proceedings will be issued as a special publication (42s., or 21s. to members) obtainable from the Secretary of the Institution at 56 Victoria Street, London, S.W.1. The registration fee of 21s. for the conference (42s. to non-members) includes a set of preprints. Application forms for registering and further information can be obtained by writing to "Symposium", Chemical Engineering Department, University, Edgbaston, Birmingham 15.

THE eighth specialized course on the design, use and maintenance of electronic instruments used in nuclear physics, radiochemistry and in work with radioisotopes will be held in the Isotope School, Atomic Energy Research Establishment, Harwell, during April 5-9. The course, which is for physicists and electronic engineers holding a degree or equivalent qualification, will be limited to twelve persons. The subjects will be entirely unclassified. The fee for the course is 12 guineas plus 5 guineas for those requiring accommodation. Application forms, to be returned by March 26, can be obtained from the Electronics Division, A.E.R.E., Harwell, near Didcot, Berks.

THE United States Office of Naval Research and the University of Pennsylvania are organizing a symposium on "The Origins of Drug Resistance, etc.", to be held in the Hotel Statler, Washington, D.C., during March 25-27. There will be five sessions as follows: origins of drug resistance in micro-organisms; effects of sciridines and resistance to insecticides and herbicides; origins of tolerance and addiction to drugs, and alcoholism; resistance factors in infectious agents and cancer cells; and physiological, chemical and genetic points of view. The symposium is open to all. Further information can be obtained from Dr. M. G. Sevag, Department of Microbiology, School of Medicine, University of Pennsylvania, Philadelphia 4, Pa.

ENGINEERING DIMENSIONAL METROLOGY

SYMPOSIUM AT THE NATIONAL PHYSICAL LABORATORY

THE National Physical Laboratory, Teddington, in co-operation with the Mechanical Engineering Research Laboratory, East Kilbride, recently organized a three-day symposium on engineering dimensional metrology, held at Teddington, during October 21-24, at which forty papers were presented and discussed. Some six countries, in addition to the United Kingdom, were represented by delegates drawn from research organizations and industry. The symposium was opened by Sir Edward Bullard, director of the National Physical Laboratory, who, in welcoming the delegates, commented on the wide field of engineering represented by those present. He spoke of the constant need for proper co-ordination between research and industry, and explained that these symposia at the National Physical Laboratory were intended to maintain and strengthen the bond. In introducing Mr. F. H. Rolt, superintendent of the Metrology Division at the Laboratory, Sir Edward mentioned that Mr. Rolt would shortly be retiring, and referred to this symposium as a fitting 'swan song' for him.

Mr. Rolt's address briefly outlined the history of the National Physical Laboratory, and spoke in some detail of the work of the Metrology Division and its contributions to the scientific and practical applications of measurement in industry. He was followed by the director of the Mechanical Engineering Research Laboratory, Dr. D. G. Sopwith, who described the progress of his Laboratory, which had been founded on a nucleus of sections transferred from Teddington. When completed, this Laboratory should be a fitting counterpart to its parent body in the field of mechanical engineering research.

The first two working sessions were devoted to 'Workshop Inspection', under the chairmanship of Mr. S. J. Harley (Coventry Gauge and Tool Co., Ltd.), who was director of jigs, tools and gauges at the Ministry of Supply during the Second World War, and Mr. J. E. Sears, former superintendent of Metrology Division, National Physical Laboratory, respectively. Dr. H. Törnbohm (Aktiebolaget Svenska Kullagerfabriken, Sweden) dealt in his paper with the wear of gauges, and mentioned how improved design, as well as the use of chromium plating and hard-metal gauging faces, can noticeably increase gauge life. Comparisons between gauging and measuring methods were made in a paper by Prof. G. Berndt (Dresden Technical College, Germany), who contended that, unless the form of the work-piece is geometrically correct, the shape of the measuring anvils or gauging surfaces is often of more importance than the choice of the measuring method itself.

An interesting optical method of inspecting profiles of turbine blade sections was the subject of a paper by M. J. Turrettini (Société Genevoise, Switzerland). The instrument described defines the profile of the blade by illuminating it with a thin belt of light, and the magnified image of the profile is then projected on to a viewing screen. With this method it is even possible to view shrouded sections and, by means of a prism assembly rotated at a suitable frequency, two sections in different planes of the blade can be viewed simultaneously owing to

the effect of the persistency of vision. Another special-purpose instrument, described by Mr. O. O. Taylerson and Mr. A. Turner (National Physical Laboratory), is used for the measurement of internal diameters to an accuracy of ± 0.00001 in. The measurements are made by a pivoted stylus arm to which are attached two mirrors. Differences in size between the diameter being measured and a slip-gauge reference standard produce angular movements of the mirrors, which are measured by means of an autocollimator with an eyepiece scale calibrated in units equivalent to 0.00001 in. Other papers dealt with methods developed in France and Germany for the measurement of screw threads, particularly taper screw gauges to the specifications of the American Petroleum Institute.

M. Vercoûtère (Compagnie Internationale des Machines Agricoles, France) described how the introduction of statistical quality control has assisted the manufacture of agricultural machinery, not only by revealing trends in production but also by giving the machine operators added information on the quality of their work and thereby stimulating their interest in it. This psychological value of quality control was also emphasized by Dr. B. P. Dudding (General Electric Co., Ltd.) in his paper on statistical techniques. The increasing use of mechanized inspection for such difficult work as turbine blades was the theme of Mr. J. Loxham's paper (Sigma Instrument Co., Ltd.), which described multigauging machines incorporating pneumatic indicating devices. Another paper, this time from France, by M. Chalvet (Ministère de l'Industrie et de l'Énergie), dealt with the application of electronics to workshop inspection. During the ensuing discussion it was mentioned that work is being done on the development of electronic devices for gathering and presenting information at present shown in quality-control charts, and the future use of electronics for supplying information to the machine tool and controlling it during its production cycle is also envisaged.

The building of measuring devices into machine tools so as to assist in the dimensional control of the product was advocated in a paper by M. R. Yribarren (Société d'Application de Métrologie Industrielle, France) in the session devoted to pneumatic gauging. It was stated that the introduction of such methods is being delayed by some hesitancy on the part of the operator to accept them for fear that they would lead to loss of craftsmanship, and also on the part of the machine-tool manufacturer for fear that the provision of a measuring device might be interpreted as an admission of functional inadequacy. Much interest was shown in the papers on pneumatic gauging. One, by Mr. L. Polk (Sheffield Corporation, United States), gave a review of developments in the United States, with particular reference to the flow-type of gauge, while another, by Dr. J. C. Evans and Mr. I. G. Morgan (National Physical Laboratory), illustrated the flexibility of the pneumatic gauging technique from examples developed at Teddington during the past five years and ranging from the continuous measurement of fuse wire to the accurate measurement of internal diameters. A quite different application was dealt with in the paper by Dr. K.

Hild (Physikalisch-Technische Bundesanstalt, Germany), which described the use of a pneumatic indicating device in the proving rings used for calibrating load-measuring devices. This session was under the chairmanship of Dr. H. Barrell, who has succeeded Mr. Rolt as superintendent of the Metrology Division, National Physical Laboratory.

A concurrent session on "Machine Tools" was held with Sir William Stanier (Power Jets, Ltd.) in the chair. Increased accuracy in the product has necessitated improvements in machine tools, and Dr. D. F. Galloway (Production Engineering Research Association) emphasized in his paper the value of dynamic, as well as static, metrological tests on machine tools, and also the desirability of testing these machines under load. An autographic method of recording the pitch errors of lathes under running conditions has been developed during recent years at the National Physical Laboratory and was the subject of a paper by Mr. F. H. Rolt. By analysis of the records produced by this method, the sources of error can be traced and, as the test is a dynamic one, irregularities in pitch due to breakdown of lubricating films can be detected. Other papers in this session dealt with methods employed at the Laboratory for testing the accuracy of jig boring machines, and a special lathe for impressing up to 30,000 threads to the inch on highly polished cylinders was described. From the threaded cylinders produced on this lathe, diffraction gratings are obtained by means of the Merton-N.P.L. process—a replica method which eventually, it is hoped, will provide large gratings of very high quality at a low cost compared with the earlier conventional ruling methods. The electronic counting of the 'moiré' bands produced when two diffraction gratings are suitably superposed may be used in the future as an accurate means of controlling linear displacements in measuring machines and machine tools.

Developments in gear metrology at the Mechanical Engineering Research Laboratory were mentioned by Mr. C. Timms in his paper during the session devoted to "Gear Measurement". Examples were given of the use of autographic recording devices in the measurement of both gears and gear-cutting machines, and the conversion of one measuring machine from manual to fully automatic operation enables the measuring of a gear to be made in one-sixteenth of the previous time. During this session, which was under the chairmanship of Dr. H. E. Merritt (Humber, Ltd.), other papers dealt with measuring techniques associated with modern gear-shaving methods and also recent developments in rolling gear testers.

A session devoted to education ran concurrently with that on gears, and Mr. H. J. Shelley (Ministry of Education) was in the chair. The two papers in this section of the symposium dealt with the teaching of engineering dimensional metrology at university and at technical college level, respectively. Prof. H. Wright-Baker (College of Technology, Manchester) referred to metrology as a means to an end in which ever science it is used, and spoke of its disciplinary value to students in achieving precision in their work; the equipment and scope for teaching engineering metrology at Manchester were referred to in some detail. Mr. V. W. Clack (Wandsworth Technical College), in introducing his paper, mentioned that every year about eight students are being trained as designers to each one that is trained as a production engineer. He based this rather disturbing statement

on the examination results, which show that annually about three thousand Higher National Certificates in mechanical engineering are awarded compared with about three hundred and seventy-five in production engineering. Mr. Clack's paper described teaching methods and equipment used at Wandsworth, and contained numerous illustrations of demonstration models of great value for instructional purposes.

Mr. G. A. Whipple (Hilger and Watts, Ltd.) presided at a session on "Small-Scale Metrology" which dealt with problems of measurement associated with the manufacture of watches and small screw threads. Mr. K. J. Hume (National College of Horology) discussed applications of metrology in the horological industry, among which he mentioned the insertion of jewel bearings in a liquid of similar refractive index so as to render possible the inspection of their section by optical projection. The production of very small screw threads down to 1 mm. in diameter and 0.1 mm. pitch, together with the measuring problems associated with this class of work, was dealt with in a paper by Mr. P. R. Brierley (Anglo-Swiss Screw Co., Ltd.).

The subject of "Large-Scale Metrology" provided a contrast to the previous papers, and this session, which was under the chairmanship of Sir Stanley Rawson (Costain John-Brown, Ltd.), illustrated very clearly the difficulties associated with large-scale measurement and also the scope that remains for development in this field. In order to assist the International Organization for Standardization in assigning suitable tolerances to interchangeable parts of large size (greater than 20 in.), investigations are being undertaken in Britain and on the Continent of Europe to assess the accuracy of the industrial measurement of large work-pieces. Two papers were concerned with this work, and in one of them Prof. N. N. Sawin drew largely on the experience of the Skoda Works, Pilsen, to describe in detail the many difficulties encountered in the measurement of large dimensions. An interesting feature was the use being made of wood in the construction of large measuring instruments. When suitably proofed against humidity effects, wood (pine in particular) provides a light stable instrument-frame that is negligibly affected by changes in temperature. The use of wooden-framed instruments was also mentioned in the paper by Mr. T. P. Jolly (English Electric Co., Ltd.), which described measuring methods used in the British heavy electrical industry.

A method evolved in the United States for overcoming the difficulties experienced in manufacturing accurate jigs for aircraft frames was the subject of a paper by Captain O. S. Reading (United States Coast and Geodetic Survey), who paid a tribute to the lead that British optical measuring-instrument manufacturers have given in this field of metrology. How precise measurement contributed to the atomic energy project was revealed in the paper by Mr. V. B. Heasen (Ministry of Supply) on the construction of the atomic pile BEPO at Harwell. Yet another application of large-scale metrology, namely, checking the profiles of large marine propellers, was dealt with in a paper by H. C. Garlick and P. W. Harrison (National Physical Laboratory).

Mr. J. E. Baty (chairman of the Surface Finish Committee of the British Standards Institution) was in the chair for the session on "Surface Finish". The first paper, by M. A. Mirau (Laboratoire Central de l'Armement), dealt with the measurement of surface finish in France, where particular emphasis has been

placed on optical methods of measurement. Besides describing a simplified form of microinterferometer which he has developed, M. Mirau dealt with other optical methods for assessing the bearing area and also the quality of polish of surfaces. The complexity of the practical aspects of surface finish of mating parts was discussed in the paper by Mr. R. E. Reason (Taylor, Taylor and Hobson, Ltd.), reviewing developments and trends in this field. Mr. D. B. Ebsworth (Bristol Aeroplane Co., Ltd.) described methods employed in the production of fine surfaces to the exacting requirements of the aircraft industry. In this work a fine surface finish is required, not only to minimize hand fitting and the period of running-in, but also to reduce the risk of fatigue failure, which so often starts from minute surface defects on the highly stressed components.

On the morning of October 24 the Metrology Division of the National Physical Laboratory was opened to delegates, who were able to see the measuring equipment and methods employed at the Laboratory and also exhibits of equipment arranged by a number of the authors of papers.

H.M. Stationery Office will publish the proceedings of the conference, and these will contain the texts of the papers and a report of the associated discussions.

T. R. J. OAKLEY

THE POTATO ROOT EELWORM AND ITS CONTROL

THE Association of Applied Biologists held a symposium on "The Potato Root Eelworm" at the Imperial College of Science and Technology, London, on January 8, which was well attended and presented a wealth of detailed work, including a demonstration of economic control under certain conditions; some hope for the production of potatoes resistant to the eelworm was also raised. The chairman, Dr. I. Thomas, outlined the magnitude of the problem. Although it is seventy-three years since eelworm cysts were found on potato roots, it was not until 1913 that severe disease was reported from Scotland and Rostock, and the organism was afterwards named *Heterodera rostochiensis*. Since that time, the disease has spread to many parts of the world, half a million acres of arable land being affected in England alone during 1949. About 150,000 acres of potatoes are attacked annually, one-third seriously, giving an overall loss of some 200,000 tons of potatoes worth £2,000,000. In advisory work alone, questions of potato root eelworm absorb a major share of the activities of 80-100 workers who spend about 40 per cent of their time on nematological problems. This last statement by Dr. Thomas seemed, more than any other, to impress members of the conference with the serious nature of the problem.

The morning session was devoted to papers on the hatching of eggs from cysts, and on progress in breeding potatoes resistant to the eelworm. It is vital, in any experimental work with potato root eelworm, to know how many of the contents of the resistant, 'dormant' cyst are still potentially active, and this can be measured by treating the cysts with 'potato root diffusate'—the drainage from potatoes grown in sand culture. Eggs within the cyst hatch into larval eelworms under the stimulus of this

liquid, just as they would when potatoes are grown on eelworm-infested land. Dr. D. W. Fenwick gave the results of his extensive studies of this laboratory measurement. When the numbers of larvae emerging from the cyst are plotted against the logarithm of time in days, a symmetrical sigmoid curve is obtained. Application of probit technique gives a linear relation. Dr. Fenwick then proceeded to show that, since the total number of larvae emerging is twice the number obtained at the point of inflexion of the sigmoidal curve, much time and space can be saved in laboratory determinations, for numbers only need to be estimated for a time sufficient to establish the point of inflexion. The slope of the probit line is a measure of the susceptibility of cyst contents to root diffusate. Practical findings checked by these theoretical considerations include several important items: temperatures between 10° and 25° C. have little effect on the total hatch, although the rate of hatching increases with rise in temperature; hatching is virtually inhibited at 30° C.; pre-soaking of the cysts in water hastens hatching; pH of the root diffusate has no effect between 3.0 and 8.0; sunlight almost inhibits hatching; hatching in a given sample is proportional to the logarithm of the concentration of the diffusate; and since the activities of root diffusate are inhibited in steam-sterilized soil for some weeks, its action appears to be linked with the microflora.

Mr. T. G. Onions spoke on the pattern of hatching from the cyst. He has subjected cysts to the action of root diffusate for a period, and then sectioned them for microscopic examination, to see where the empty, hatched eggs lie. He found most near the vulval end of the cyst, and obtained more from the periphery than from the middle. It was thought that this pattern of hatching might reflect a gradient of oxygen tension.

It would be a great advance in control if potatoes could be bred with resistance to the potato root eelworm. Mr. F. G. W. Jones reviewed the possibilities and progress of this approach. Resistance to this particular eelworm is found in *Solanum ballii* (= *vernii*) and also in *Solanum andigenum*, which may be no more than a variant of *S. tuberosum*. German workers are investigating the possibilities of introducing resistance through crossing potatoes with *S. ballii*, and Dutch and British workers are using *S. andigenum* as the resistant parent. The mechanism seems to be that of a dominant gene responsible for resistance, with tetrasomic inheritance giving the possibility of all degrees of resistance and susceptibility. Practical degrees of resistance as yet attained are rather low; but it might be useful to approach the problem of resistance through some contributory issue. Crosses between *S. stenotomum* and *S. vernii*, for example, have low cyst-hatching stimulus which may add, in practice, to their resistance. Another possible line of approach would be to combine high cyst-hatching stimulus with innate resistance, in order to provide the ideal trap crop, and thereby reduce the effective eelworm population.

The afternoon session on direct control opened with a paper by Dr. B. G. Peters on "Laboratory and Pot Tests of Nematicides". These tests are a first stage in assessment of the value of any material for such control. A certain amount of knowledge can be obtained quickly by dispersing a toxicant under test in water and inoculating it with the vinegar eelworm in a special double-flask culture apparatus. Dr. Peters also described the necessary controls and measurements to obtain the maximum

information from pot experiments—to make allowance for natural death, variations in eelworm population, and other factors. He has, indeed, reduced the technique of such tests to a process as exact as possible, and gave examples of their use with D.D. mixture (dichloropropane–dichloropropylene), ethylene dibromide and other materials. A typical useful practical result from pot experiments is that a single injection with D.D. gave a percentage kill of larvae superior to that with two or three consecutive injections.

Dr. J. Grainger described an economic field control with D.D. on first-early 'Epicure' potato crops in Ayrshire. Increases in yield in numerous experiments since 1947 have been worth about twice the cost of treatment, whether applied at 200 lb. or 400 lb. an acre. Later-lifted crops do not command such high prices a ton as first-earlies, and the yield increase only equals the cost of treatment. Evidence was given for the belief that D.D. has a three-fold action: it can diminish the number of larvae within cysts; it can diminish the number of full eggs in the cyst in the absence of potatoes; and it can stimulate growth of the potato crop directly. Long-term experiments on possible control of potato root eelworm on main-crops grown in a seven-year rotation were described. They are designed to make the best use of the three-fold action, which also supplies the reason for treating first- and second-early crops as long as possible before the potatoes are planted. Dr. Grainger also briefly described his 'Auchinaruive' soil injectors for the application of D.D.; these are now in commercial production. Several results indicated that, for equal quantities an acre, the performance of D.D. was superior when injected as 'spots' at 15-in. centres rather than in continuous traces 12 in. apart. Other materials showing sufficient promise to be investigated on a field scale are ethylene dibromide and inorganic compounds of mercury. These both appear to lessen the build-up of the eelworm population when potatoes are grown, and mercury compounds would be much cheaper than D.D. if they could be mixed finely enough with the soil.

An interesting study on possible control was described by Mr. L. N. Staniland. Phenols, cresols and xlenols and their chlorinated forms give some control of potato root eelworm; but their performance is greatly improved by 'solubilization' with detergents, preferably of the long-chain alkyl sulphate type. They are used as soil drenches at 1 gallon/sq. ft., and at present are quite uneconomic for field application. In the glasshouse, their use is cheaper than steam sterilization, but dearer than D.D. There is, moreover, a danger of tainting the crop. In spite of all these present economic handicaps, however, Mr. Staniland described ways in which performance could possibly be improved. Lower concentrations with more detergent, the introduction of small amounts of iodine, and the performance of different chlorinated compounds are all under test, and Mr. Staniland's audience felt that whether the study ultimately developed economically or not, it would be a sound contribution to the problem.

Prof. H. W. Miles opened the discussion on the morning session of the conference. He said that eelworm study was somewhat neglected in the past, and that the approach to the problem first arose from the farmer. Host-parasite relations are most important for a correct understanding of the problem, and laboratory work is beginning to equal that

devoted to the practical approach. Discussion during the afternoon session was initiated by Dr. W. Healey, who thanked the Association for the opportunities afforded by the symposium, and summarized the economic considerations of direct control arising from the lectures. The use of D.D., he said, comes nearest to practical control at present. It has been suggested that its action might in practice be indirect, putting host and parasite somewhat out of phase. Interesting matters arising from the general discussion are that the breakdown of cysts is slower in peat soils than in loam (Dr. Fenwick), and that potato root eelworm has been found in Peru, one of the native homes of the resistant *Solanum* species. These species are, however, less resistant to the Peruvian strain than to the European eelworm (Dr. C. Ellenby). The question was also raised as to whether a seven-year rotation would itself control infestation of potato root eelworm in practice. Dr. Grainger maintained that the period is not long enough, and certainly not in west Scotland. Infestations capable of causing disease can persist there for 20–25 years in the absence of potatoes. Such results are to be expected by calculation from experiments on the rate of natural loss, and have been confirmed by authenticated advisory cases.

THE RUBBER RESEARCH INSTITUTE OF MALAYA: BOTANICAL DIVISION

THE botanical work of the Rubber Research Institute of Malaya, Kuala Lumpur, for the years 1949–51, as presented in its report, is by way of being an interim account of the five-year plan begun in 1949. Important new developments and discoveries, relating to the extensive investigations now in progress, are briefly indicated under the headings of breeding and selection, propagation and planting techniques, tapping, physiology, and ecology. The programme on breeding and selection deals with such items as pollination, the large-scale production of improved seedlings, cytogenetical studies of *Hevea*, the examination of criteria for selection in the laboratory and in the field, the selection of individuals and clones based on their vegetative characters, the quality and properties of latex and rubber, and selection for resistance to disease, etc.

Studies of propagation and planting technique have related to such matters as the effectiveness of bud-grafting on to mature root systems, the pre-budding treatment of budwood, the storage of *Hevea* seeds, stock-clone relationships, density of planting and distribution, the effect of selective thinning-out, the value of mixed planting of *Hevea* and other crops, for example, cacao, and methods of new planting and replanting. Work on tapping has been concerned with tapping systems for seedling and budded trees and slaughter tapping experiments. Physiological studies of the nutrition of *Hevea* have been continued, attention being paid to the cause of the chronic defoliation in certain clones and to latex flow in response to tapping. Researches of a more fundamental character on the physiology of latex are also in progress. The effects of various injected substances, for example, copper salts, on the yield and properties of latex, and the stimulation of latex

yield by the application of emulsions of various growth-regulating substances, are also being studied. An unusual, if somewhat contemporary, flavour is introduced by the inclusion in the report of instances of sabotage in the experimental fields by terrorists.

VERY-HIGH-FREQUENCY BROADCASTING IN GREAT BRITAIN

IN its first report last year the Television Advisory Committee made recommendations to the Postmaster-General regarding the future of television broadcasting in Great Britain (see *Nature*, August 22, 1953, p. 337). At that time it was stated that the Committee's next task would be to investigate the introduction of high-frequency sound broadcasting as an additional system to the medium- and long-wave transmissions already used by the B.B.C. for its programmes, and now the Committee has published, as its second report*, its recommendations on this score.

The problem before the Committee and its Technical Sub-Committee is that the existing medium- and long-wave services are barely adequate for supplying the general and regional programmes, that they allow no scope for expansion and that, in fact, they are threatened with progressive deterioration owing to the increased interference from Continental stations, mainly those not bound by the Copenhagen Broadcasting Agreement. It is for the most part accepted that the general plan for tackling this problem is to utilize Band II of the frequency spectrum, namely, the very-high-frequency band of 88–100 Mc./s. (3.4–3 m.) that has been allocated by international agreement to Great Britain for sound broadcasting; because the top part of this band is already used by Civil and other services, this in practice reduces the band to the range 88–95 Mc./s. For most broadcasting, such as the existing B.B.C. programmes (including the sound channel of television), the audio-frequencies are impressed on the carrier wave by the method of amplitude modulation; but very-high-frequency waves do offer the practical alternative of frequency modulation, and the Technical Sub-Committee has gone to great lengths to decide which form of modulation to use. This is a problem of many facets, but the main feature that one must assume is that most receivers will have comparatively poor aerials and that most reception areas will be partly screened and subject to a not inconsiderable amount of electrical interference (for the most part amplitude-modulated). For a service comparable with the sound programmes received on long- and medium-waves, the median value of an amplitude-modulated signal at 90 Mc./s. would need to be 1.5 mV./m. generally and 5 mV./m. in large towns; for the same grade of service on frequency-modulation, the signals need only be 0.25 and 0.8 mV./m., respectively. An interesting point noted in the report is that the signal-to-noise ratio of the sound received in conjunction with television is extremely poor, the amplitude-modulated signals at 45 Mc./s. (at which frequency the standard dipole is twice as efficient as one designed for 90 Mc./s.) being about 0.1 and 0.35 mV./m. for the two types of

locality; but from a psychological point of view, the associated visual picture masks the poor signal-strength of the sound.

There are, in fact, three possible types of very-high-frequency broadcasting: frequency-modulation at ± 75 kc./s. deviation, requiring a channel separation of 200 kc./s.; narrow-band amplitude-modulation (channel separation 15 kc./s.); and wide-band amplitude modulation (channel separation 200 kc./s.). For each of these systems to cover 97 per cent of the population of the United Kingdom with three national programmes, the frequency-modulation needs to transmit a total of 760 kW. from 77 transmitters (theoretically 25 per programme, but two extra are needed for Welsh programmes), while the two amplitude-modulation systems require 2,800 kW. from 108 transmitters; the corresponding capital outlays are estimated at £3.5 million and £9 million, respectively, and the annual costs at £800,000 and £2 million. These figures assume a common mast and aerial system for the radiation of three programmes in each area. But the figures for amplitude-modulation are worsened even further if the transmissions in any one area were restricted to a single 600-kc./s. band; for then, due to filtering difficulties, it would be necessary to use three separate, widely spaced masts, or increase the power considerably in a single mast, and in either case the capital and annual costs would be very much increased for such an installation, perhaps as much as doubled.

The report devotes considerable space to the question of receivers, because obviously the introduction of very high frequencies would entail the production of entirely new sets or the adaptation of existing ones, and this is a matter of very great financial importance both to the radio industry and to the public. Though narrow-band amplitude modulation appears on the surface to offer certain advantages, there are in fact considerable difficulties, the principal ones being that oscillator drift in the receiver must be held to the fine limits of 2 kc./s., and it would be very difficult to allocate frequencies which would entail freedom from certain types of interference and also the propagation of interference in the 41–68 Mc./s. band from the receiver oscillator. Thus the choice really narrows down to wide-band amplitude-modulation or frequency-modulation, and as far as receivers are concerned, whether they be adaptors for existing sets or new sets designed for very-high-frequency reception, there seems little to choose between the two systems. As a matter of interest, although adaptors are discussed fully in the report, it is considered that they will be required for only a limited time and that the market for equipment receiving very-high-frequency radiation will eventually be concerned solely with sets designed exclusively for the new type of radiation. Thus the advantage of frequency-modulation is more or less based on the transmitter point of view, though this is not inconsiderable.

The Committee therefore recommends that very-high-frequency broadcasting using frequency modulation should be established in Great Britain, and that this holds good whether sufficient stations are eventually put up to give a national coverage on three programmes or whether the number is sufficient only to provide a substantial reinforcement of the services now given on the long- and medium-waves. This recommendation is signed by nine of the ten members of the Committee, and the dissenting member, Mr. C. O. Stanley, one of the representatives

* General Post Office: Second Report of the Television Advisory Committee (1953). Pp. 25. (London: H.M.S.O., 1954.) 1s. net.

of the Radio Industry Council, has submitted a minority report which is printed in full after the majority report, together with a point-by-point reply by the other members of the Committee to Mr. Stanley's views.

The main feature of Mr. Stanley's arguments is that he does not accept the assumption that very-high-frequency broadcasting need necessarily be introduced in the first place, and that, if it were, the experience of other countries that have introduced it, most of them using frequency-modulation, is decidedly unfavourable. If the plans for very high frequencies go ahead, then the general public will have to start considering buying a completely new receiver, the cost of which for an amplitude-modulator set would be, on the average, £20 and for an equivalent frequency-modulation one £30. Mr. Stanley thinks that the future for the existing broadcasting systems is not necessarily hopeless and that the Committee's first task should be to investigate what may be done to improve them rather than replace them. The reply of the majority of the Committee is that very-high-frequency broadcasting is an unwelcome but inescapable complication, and that its introduction will probably be spread over at least ten years. During that time existing sets owned by the public will tend to wear out and need replacement, and the higher cost of a frequency-modulation receiver is more than outweighed by the advantages of the system.

As in the case of the report on television, the Committee's terms of reference are for the most part concerned with technical problems; but the expansion of television and the introduction of very-high-frequency broadcasting both involve heavy capital outlay by the Government and the development by industry of a wide range of new products, together with the necessity of the general public to find the money for purchasing these products. These are grave economic factors and will, no doubt, be an important, if not over-riding, consideration in any Government decision on these matters.

HORIZONTAL DISPOSITION OF RHIZOMES

THE diageotropic disposition of the rhizome in bishop's weed (*Aegopodium podagraria*) has been attributed by T. A. Bennet-Clark and N. G. Ball (*J. Exp. Bot.*, **2**, 189; 1951) to the action of two hormones working in opposition to one another; both are affected by gravity, and the horizontal position of the rhizome is due to an equilibrium between the effects of the two hormones.

N. G. Ball has now taken the investigation of the mechanism of this intriguing problem—the horizontal disposition of rhizomes—a stage further by examining the effects of several known growth-regulating substances on *Aegopodium* rhizomes (*J. Exp. Bot.*, **4**, 349; 1953). The experimental treatments, which involved the immersing of rhizomes for periods of forty-five minutes in solutions of the growth-regulating substances, were carried out in the absence of visible light, the rhizomes being photographed every hour by infra-red radiation. After immersion in 10^{-4} M β -indoleacetic acid the rate of rhizome growth is approximately doubled; but about five hours later it declines to one-third or less of its original value and then gradually recovers.

This depression in the growth-rate can, however, be reversed by a second auxin treatment, the inference being that the exhaustion of some substance necessary for growth is not involved. It is suggested that the auxin which first accelerates elongation may later be converted into, or may cause the production of, an inhibitor. Thus, when successive immersions in auxin are repeated every two hours, the inhibition can be partially overcome as long as the treatment is continued. As the immersion of horizontal rhizomes in the growth-regulating substance also causes them to turn up, this is taken as giving support to the hypothesis indicated above; that is, an equilibrium is disturbed.

Thus it would appear that when a rhizome is immersed in a solution of auxin there is some mechanism which causes the auxin to accumulate on the lower side. As this may also be assumed to happen to any auxin produced in the rhizome itself, a probable explanation appears to be that the horizontal position assumed by the rhizome results from the balancing of the excess hormone on the lower side of an opposing one. It is pointed out that if the suggestion that β -indoleacetic acid causes an acceleration of growth followed by an inhibitory effect, or that it may itself be converted into an inhibitor, should prove to be generally valid, it would afford a simple and satisfactory explanation of autotropism. The effects of 2:4-dichlorophenoxyacetic acid, ascorbic acid, 2:3:4-triiodobenzoic acid and 2:4-dichloroanisole were also investigated.

STRUCTURES OF NATIVE AND MERCERIZED CELLULOSES

By DR. M. K. SEN and DR. S. C. ROY

Indian Jute Mills Association Research Institute, Calcutta

IN a previous publication, Sen and Woods¹ reported the presence of two new equatorial reflexions in the diffraction pattern of native celluloses of various origins. Continuation of this work with more detailed experimentation has now made it possible to make certain assertions with regard to the origin of one of the reflexions, Y. From X-ray photographs taken under various conditions of prevailing humidity, intensity and purity of radiation (including monochromatic radiation) and with different cellulose samples, such as ramie, jute, cotton, viscose and paper, it has been noted that the reflexion occurs in greater or less intensity in almost all ordinarily available cellulose fibres, native or mercerized. Under conditions of 60–70 per cent relative humidity and 70–75° F. temperature, the sharpness, intensity and dispersion of the diffraction maximum are at least equal to those of certain other equatorial reflexions (Fig. 1). The observations regarding its relative intensity in different samples when compared against Meyer and Mark 101 are summarized in Table 1.

Table 1

Samples	Intensity
1. Defatted white jute	Slightly less than that of 101 reflection.
2. Commercially degummed ramie	Less than that of 101.
3. Surgical cotton	Less than that of 101.
4. Ordinary rayon	Slightly less than that of 101.
5. Pre-swollen rayon (treating with ethylene diamine, washing and drying)	Slightly less than that of 101.
6. Mercerized ramie	Greater than that of 101.
7. Mercerized jute	Greater than that of 101 (mercerized).

Fig. 1. X-ray photographs with copper $K\alpha$ at 30 kV. and 20 m amp. (a) Native ramie; (b) native jute; (c) native cotton; (d) mercerized ramie; (e) mercerized jute; (f) viscose

In point of sharpness, reflexion Y not only invites comparison with other equatorial spots but in some cases even exceeds them. Its dispersion across the equator runs parallel with the dispersion of the other reflexions and, in relatively more extensible materials such as mercerized ramie and mercerized jute, becomes reduced on progressive stretching.

The spacing at room condition (60–70 per cent relative humidity and 70–75° F. temperature) corresponding to the reflexion for different samples is shown in Table 2.

Table 2

	Spacing (Å.)
Native jute	14.3
" " delignified	13.6
" " alkali-treated (0.3%)	13.6
" " " (1.0%)	13.6
" " " (5.0%)	13.6
" " mercerized without tension	14.0
" " mercerized and stretched (16% shrinkage allowed)	14.0
" " mercerized and stretched (4% shrinkage allowed)	14.2
Native ramie	13.6
" " mercerized without tension	14.7
" " mercerized and stretched (16% shrinkage allowed)	14.4
" " mercerized and stretched (4% shrinkage allowed)	14.5
Cotton	13.1
Viscose	14.8

It is therefore concluded that the reflexion originates from the cellulose crystallites. The difference in the intensity and the variation in the spacing for different samples should arise from the formation of mixed crystals with other polysaccharides and/or absorption of water, which may be the water of hydration or the structural water.

Attempts were made to fit the new reflexion into the reciprocal lattice nets as obtained from the unit cells due to Meyer and Mark⁴, Sauter⁵ and Andress⁶. It was found that none of the hitherto accepted unit cells could account for this reflexion. From analysis of our photographs, it has been possible to fit all the reflexions from native and mercerized ramie as ordinarily obtained into two different unit cells the parameters of which are as follows:

Native cellulose	15.6 Å.	10.3 Å.	12.5 Å.	66°
Mercerized cellulose	16.3 Å.	10.3 Å.	9.0 Å.	64°

The observed and the calculated values of the spacings and the corresponding indices of the planes are shown in Tables 3 and 4.

The cells apply also for cotton, jute and other cellulosic fibres, the only difference being in the slight shift in the 100 plane and hence a small change in the dimensions on account of the inclusion of water or other polysaccharides.

We believe that the Meyer and Mark, as well as Andress, cells for native and mercerized celluloses do not represent the structure of the material under ordinary conditions of temperature and humidity. On the other hand, the cells proposed account for all the reflexions as obtained from flat-film rotation photographs. Furthermore, the theory of the impenetrability of cells of native cellulose by water does not seem tenable, because, as is evident from the changes on moisture absorption in the spacing

due to the 100 plane in native cellulose and those due to the 100 and 200 planes in mercerized celluloses (see also Sen and Woods¹, and Mukherjee and Woods²), varying amounts of water can remain within the cells. This being so, the current concept of the crystalline and non-crystalline regions perhaps needs revision. The ideas might perhaps be best expressed in terms of accessible and inaccessible regions and perfect and imperfect crystallinities, there being no sharp line of division between the two.

The failure of previous workers to observe the newly found reflexion are ascribed to: (a) use of

Table 3. hkl , d_{hkl} and d_{obs} values (native ramie)

hkl	d_{hkl} (Å.)	d_{obs} (Å.)	hkl	d_{hkl} (Å.)	d_{obs} (Å.)

404	2.23	2.21	223	2.59	2.58
210	5.97	6.02	023	2.39	2.38
012	3.77	3.78	031	3.16	3.14
412	3.41	3.38	132	2.71	
212	2.90	2.91	431	2.62	2.62

large primary beam stop, (b) absorption in fibre bundles due to very thick specimens, (c) use of Sauter camera capable of recording reflexion only within limited angular range, (d) perhaps very dry condition of specimen, the intensity of the reflexion decreasing with the loss of moisture, and (e) low collimation ratio in certain cases and therefore lack of sufficient resolution.

Our results at present do not permit us to draw any conclusions concerning the structure of cellulose in a perfectly dry condition (that is, without the chemically combined last trace of water), and so nothing can be said regarding the validity or otherwise of the unit cells due to Meyer and Mark and Andreas for perfectly dry fibres. A detailed communication on the various issues and far-reaching implications likely to be involved in this new finding is being published elsewhere. Investigation into the probable space-group symmetry is in progress.

DYE-SENSITIZED PHOTOPOLYMERIZATION

By DR. GERALD OSTER

Institute of Polymer Research, Polytechnic Institute of
Brooklyn, Brooklyn 2, New York

FREE radicals, except the most stable ones, will initiate the polymerization of vinyl compounds. The free radicals may be produced by the direct photolysis of the monomers, but this requires light of wave-length well into the ultra-violet spectrum¹. Light of nearly ultra-violet wave-length (~ 3000 Å.) will cause the breakdown of substances such as benzoyl peroxide into free radicals which will initiate polymerization². Irradiation of solutions of acidified ferri salts by light of this wave-length will also produce free radicals capable of initiating the polymerization of vinyl compounds³.

Attempts have been made to extend the spectral range of the photopolymerization to the visible region by using dyestuffs as photosensitizers⁴. These reactions, which were carried out in the absence of oxygen, gave low quantum yields for the conversion of monomer. I have shown that the quantum yield for the conversion of acrylonitrile to polymer in water using rose bengal as the sensitizer is considerably enhanced if the solution, irradiated with visible light, contains ascorbic acid and if oxygen is present⁵. In the present communication, the results of our experiments for dye-sensitized photopolymerizations of high quantum yield are summarized. The practical implications of this work are treated elsewhere⁶.

Acrylonitrile in aqueous solution (7 per cent in monomer concentration and buffered at pH 7.0) with fluorescein or one of its halogenated derivatives (eosin, phloxine, erythrosine, rose bengal) as the sensitizer is readily polymerized on irradiation with visible light if oxygen is present and if the solution contains a mild reducing agent. Ascorbic acid and phenylhydrazine hydrochloride are particularly effective as reducing agents, while the photopolymerization proceeds more slowly with hydroxylamine,

hydrazine sulphate, thiourea, allylthiourea, glutathione and cysteine. In the absence of oxygen, the dye is photoreduced to its leuco form with a quantum yield of about 10^{-3} , but no polymer is produced. It appears that in the presence of air, the reduced form of the dye, DH_2 , reacts with atmospheric oxygen to produce the semiquinone form of the dye DH and hydroxyl radicals, that is, $DH_2 + \frac{1}{2}O_2 \rightarrow DH + OH$. The free radicals thus produced initiate the polymerization of the monomer.

Pure liquid monomers and concentrated solutions of monomers in either water, methanol or acetone were also found to be rapidly photopolymerized when certain combinations of dye-reducing agents were present. Thus, liquid acrylonitrile is readily photopolymerized when acriflavine is used as the photosensitizer in conjunction with a small amount (10^{-4} per cent) of freshly prepared acidified stannous chloride. This reaction does not proceed in the absence of oxygen. Liquid styrene is photopolymerized when a small amount of an alcoholic mixture of rose bengal and phenylhydrazine hydrochloride is added to the system. Other monomers which have been photopolymerized by these methods include acrylic acid, methacrylic acid, vinyl acetate, and methyl methacrylate. Some dyes such as brilliant green and rhodamine B were found to be effective, whereas other dyes, such as all the triphenyl methane dyes which we tested, were found to be ineffectual. Azine dyes, particularly pinakryptol green, in trace amounts (10^{-4} per cent) are inhibitors of photopolymerization for the systems described above. It is significant that the azine dyes are also inhibitors for the photoreduction of fluorescein and its halogenated derivatives^{6,7}.

The choice of the reducing agent to be used in conjunction with a given dye is critical. In general, the reduction potentials of the dye (at a given pH) should be more negative than that of the reducing agent, so that the dye is not decolorized in the dark. Furthermore, the reduction potential of the dye should be within about two electron volts of that of the reducing agents, since this is a necessary condition for the photoreduction of the dye by visible light⁸. The concentration of oxygen present is also critical. Oxygen can participate in the photosensitized destruction of the reducing agent and will, for some monomers, inhibit the growth of the polymer chain. Uri⁹ found that the quantum yield for photopolymerization of methyl methacrylate in alcohol sensitized with chlorophyll was considerably enhanced if ascorbic acid is present; but the reaction does not proceed in the presence of oxygen. In some cases it appears that the solvent, for example, acetone, may participate in the reaction and that the semiquinone form of the dye is the active radical for the initiation of the polymerization.

Certain monomers such as N-vinyl pyrrolidone and acrylamide are themselves reducing agents. For example, aqueous solutions of acrylamide sensitized with the easily reducible dye riboflavin are readily photosensitized, no additional reducing agent being added. A 10 per cent aqueous solution of acrylamide containing 0.005 per cent riboflavin was irradiated with light from a 500-W. tungsten lamp, the sample being 45 in. from the lamp, and a blue Corning glass filter passing light mainly of wave-length 4360 Å. was interposed between the lamp and the solution. By the use of a calibrated thermopile, it was determined that 2.8×10^{-10} einsteins were absorbed by 1 ml. of the solution per sec. After an induction

period of 5 min., the monomer is converted into polymer at a constant rate and the viscosity rises very sharply, the solution becoming a stiff gel after irradiation for 30 min. The quantum yield of monomer conversion is 4,250. Much higher quantum yields are obtained using high concentrations of monomer and decreasing somewhat the oxygen concentration, although complete removal of oxygen inhibits the reaction. The molecular weight of the polymer produced after irradiation for 15 min. was found by light scattering (after carefully washing the methanol-precipitated polymer and redissolving in water) to be 8.32 millions. This extraordinarily high molecular weight may be attributed in part to the fact that the polymerization was carried out at room temperature rather than at elevated temperatures where most polymerizations (thermally initiated) are carried out.

A 10 per cent solution of acrylamide sensitized with riboflavin was irradiated with a single burst of light of millisecond duration from a large commercial photographic flash lamp. After an induction period of one hour, the viscosity of the solution gradually rises and the system becomes a stiff gel on standing 24 hr. in the dark. More concentrated solutions of monomer also show an induction period, and the solution is rapidly transformed into a hard, clear plastic. The sample becomes very hot due to the exothermic character of the polymerization. Solutions from which oxygen had been rigorously removed do not exhibit polymerization after irradiation by the flash until the vessel is opened to the atmosphere. It is clear that free radicals are not produced directly by visible light, but rather are produced by the dark reaction between the reduced dye and oxygen.

VISUAL PURPLE LEVEL AND THE COURSE OF DARK ADAPTATION

By DR. W. A. H. RUSHTON, F.R.S., and R. D. COHEN

Department of Physiology, University of Cambridge

WHEN we go suddenly from moderate light into darkness, at first we can see nothing; but over the next half-hour visibility greatly improves. Owing largely to the work of Hecht, the improvement has been attributed in the main to two factors: (a) the shift of vision from cones to rods; (b) the regeneration of visual purple bleached in the light-adapted state. With regard to (b), there is no doubt that this occurs after intense illumination, for Tanale¹ followed the process in the rat by extracting the visual purple from the eyes of animals killed at various stages, and Rushton² (with Brindley and Hagins) has measured the course of bleaching and regeneration

Fig. 1. Adaptometer with alternate light-paths so that two different test flashes may be compared throughout dark adaptation

in the living cat and albino rabbit by an optical method. But as Granit *et al.*³ have shown, there is a very serious discrepancy in the quantitative correspondence between the change of visibility and the change in visual purple content of the retina; for, light of a brightness which would alter the visibility many hundred-fold (as indicated in the animal by change in the size of the electroretinogram) was found not to have appreciably bleached the visual purple, later extracted and measured. Schouten and Ornstein⁴ demonstrated that the effect of glare cannot be explained upon a pure photochemical basis, and Baumgardt⁵ has calculated that at moderate illumination extremely little of the visual purple supply of the eye would be broken down. Our own observations have led us in the same direction, and from the evidence now to be presented we conclude that there is no detectable change in the level of visual purple in the hundred-fold increase of sensitivity which follows the extinction of an ordinary room light.

The observer himself plotted the course of his dark adaptation by moving a wedge in front of his eye so that a flash of light was only just visible (Fig. 1). The wedge movement was recorded upon a very slow smoked drum. By means of alternate optical pathways from flash to eye, each with its own recording wedges, two dark adaptation curves could be traced at a single run by arranging that the flashes came now by one path, now by the other. In this way the effects of colour, field-size, duration and retinal location of the flash could be easily compared at a given stage of adaptation. A red fixation point was used and the flashes fell at about 1 per sec., some 10° on the temporal aspect of the retina (that is, far from the blind spot). The observer first spent half an hour in the dark, then he had 20 sec. close in front of an opal glass of luminance 300 ft. L. for light adaptation; the adaptation curves were then traced in the dark by setting the wedges alternately.

The results of one typical experiment are shown in Fig. 2; they were adjusted to coincide for full dark adaptation. The test flash was green; but the same results are obtained with any colour from

Fig. 2. Threshold intensity of a just visible flash plotted against time from end of light adaptation (300 ft. L. for 20 sec.). Circles: 3° field, 1 sec. flash. Dots: 3° field, 7 msec. flash. Adjusted to coincide at full adaptation

violet to yellow-green. Orange and red, on the other hand, give an adaptation which is rapid and slight, due no doubt to cones being involved. We conclude that the curves of Fig. 2 are entirely due to rods.

Now the regeneration of visual purple must affect these two curves equally; hence the superior dark adaptation of the upper one is clearly due to other causes. But we can exclude regeneration as a cause even of the lower one. For if we assume that visual purple in the eye bleaches as it does in solution with a quantum efficiency of 1 (Dartnall *et al.*)⁴, then 20 sec. at 300 ft. L. with pupil diameter 3 mm. will bleach about 2 per cent of the visual purple present. It is not easy to escape this conclusion by supposing that in the living eye visual purple is bleached much faster than *in vitro*, for (unpublished) observations by Rushton and Hagns on the living albino rabbit show the bleaching-rate to be about the same as in solution (or a little slower). Thus in the experiment of Fig. 2, the visual purple could not increase its concentration appreciably throughout dark adaptation since at the outset it was 98 per cent of the maximum.

We must therefore turn to consider what factors could account for the increased visibility during dark adaptation which certainly occurred. These may conveniently be classified in four categories: increase in (i) the fraction of light incident upon the cornea which reaches the retina; (ii) the fraction of light incident upon the retina absorbed by the visual purple; (iii) the summation time and summation area; (iv) the quantum sensitivity.

The only likely variable under (i) is size of pupil. This could not affect our records since the light flash was focused upon the centre of the pupil in a 1.2-mm. pencil.

(ii) As we have seen, this effect cannot contribute.

(iii) An optic nerve fibre will only discharge if the receptors connected to it have caught a certain number, N , of quanta within a certain summation time. The longer the summation time and the wider the summation area, the more likely that N quanta will be caught from a flash which is extended in space and time (as in the circles, Fig. 2). But if the

flash were highly restricted in space and time (dots, Fig. 2), no increase in sensitivity would appear from cause (iii). The difference in the curves of Fig. 2 may thus be regarded as expressing the increase in summation area and time which occurs as dark adaptation proceeds, as already found by Craik and Vernon⁵. It is left unsettled whether this is a gradual increase in the size of receptive field of single nerve fibres as found in the cat by Kuffler⁶, or a change of activity from small to large fibres as suggested by Pirenne and Denton⁷. In any event, it is highly efficient, since 'information' is not lost, but by exchanging sensitivity for precision, the maximum discrimination can be secured at each luminance.

(iv) The quantum sensitivity is the inverse of N , the number of quanta necessary to excite an optic nerve fibre. Since the lower curve of Fig. 2 is not affected by (i), (ii) or (iii), it must represent simply a change in (iv) during dark adaptation.

We conclude that, in the conditions here considered, by far the chief factor in dark adaptation is an increase in quantum sensitivity of the retina.

REPRODUCTION IN MARSUPIALS

By G. B. SHARMAN

Zoology Department, University of Western Australia

RESEARCH on the problems of marsupial reproduction is at present in progress in this department. Several marsupial species are housed in the departmental enclosures; but so far systematic work, here briefly reported, has been limited to the Rottnest Island wallaby (*Setonix brachyurus* Quoy and Gaimard). This animal breeds readily in captivity, and periodical surveys carried out on Rottnest Island indicate no great differences in reproductive processes between the wild population and the departmental colony. Several papers dealing with aspects of reproduction in this animal are at present in course of preparation.

The reproductive system is anatomically similar to those of other macropod marsupials described by Pearson¹. Our records show that *Setonix* is exclusively monovular; multiple ovulations or births have not been recorded in either wild or captive populations. The animal is polyoestrous, and the recurring oestrous cycles are of approximately twenty-eight days duration. This is the same length as the oestrous cycle in the American polyprotodont marsupial *Didelphis*². In both wild and domestic populations the unfertilized *Setonix* has regular oestrous cycles between late January and the end of October. During the remaining (summer) months there is an aneostrous phase during which ovary and uterus are quiescent.

The significance and cause of the annual aneostrous are not known. Experiments are in progress to

determine whether increased daily illumination is the immediate predetermining stimulus. During the summer, the animal is exposed to periods of extreme drought, and it could be plausibly postulated that the anoestrous period has adaptive significance in preventing the extra water utilization involved in lactation during the dry period. It also has the merit of ensuring that most births take place immediately after anoestrus, the young then being sufficiently developed to leave the pouch when green feed is abundant in the following spring.

We have little information concerning the number and length of the oestrous cycles in other marsupials. Hartman² showed *Didelphis* to be polyoestrous, whereas Hill and O'Donoghue³ consider the Australian polyprotodont, *Dasyurus viverrinus*, to be monoestrous. *Bettongia orniculatus* is polyoestrous, the length of the cycle being unknown, although there may be an anoestrous period in the summer months⁴.

In wild populations of *Setonix* there is a burst of sexual activity following the annual anoestrous period, and it is at this time that the majority of young are born. Copulation takes place while the first maturation division is proceeding in the ovarian egg. Ovulation follows in mated animals approximately one day post-coitum. In unmated animals ovulation is independent of the stimulus of copulation. Parturition occurs from twenty-four to twenty-eight days after mating, most likely on day twenty-six or twenty-seven. As in the American opossum, gestation is thus shorter than the length of a normal oestrous cycle. In *Didelphis*, as in *Setonix* and most other Australian marsupials, no true allantoic placenta exists at any time during gestation. It is probable that the marsupial yolk-sac placenta, unlike the eutherian (allantoic) placenta, has not assumed pituitary and ovarian functions as a secondary source of hormones. If this is true, it may well mean that the aplacental marsupials are physiologically incapable of retaining young in the uterus for a period greater than the length of the oestrous cycle.

In fertilized animals, maturation of an ovarian follicle continues during pregnancy as in the normal non-pregnant animal. Parturition is closely followed by oestrus and ovulation, the corpus luteum of post-partum ovulation becoming the corpus luteum of lactation. This corpus luteum is maintained during the ensuing five or six months, while the young is suckled in the pouch, and retrogresses thereafter. During at least the first half of this time a lactation anoestrus occurs. Although females normally copulate at post-partum ovulation, birth of a second young does not occur while the mother is feeding an embryo in the pouch. However, females segregated from males immediately after post-parturition copulation give birth to a second young if lactation is interrupted by removal of the pouch young. This second foetus could be explained either by delayed implantation or by the prolonged storage of sperm. Delayed implantation in rodents is known to be due to the feeding of large litters by the pregnant mother. Although the uteri of lactating *Setonix* present no external differences from those of the non-pregnant animal, these were subjected to thorough search in serial section. In several lactating animals which had copulated at post-partum heat a small unimplanted blastocyst 0.3 mm. in diameter was found in the uterus; blastocysts have also been recovered whole by flushing the uterus with saline.

The unimplanted blastocysts of lactating *Setonix* can certainly proceed to normal development after a quiescent period of four months; some evidence indicates that they may remain viable for periods of about eight months in this state of suspended animation. It appears, therefore, that we have a sufficient explanation of delayed parturition in terms of 'stored unimplanted blastocysts'. As an additional confirmation of this conclusion, we destroyed the Fallopian tubes in two females suckling pouch young, so that no new eggs could enter the tract. The suckling young were removed from both. Two days later, the uterus of one mother was flushed out and a small blastocyst recovered. Eleven days after the operation the uterus of the second mother was similarly treated, and a large actively dividing embryo recovered.

In all Eutheria investigated, with the possible exception of the bat⁵, sperm may have a very short life in the female tract. So it would be surprising if storage of sperm in the marsupial female tract were a reason for delayed parturition. At best, of course, it could only be a cause supplementary to the delayed implantation described above. Nevertheless, careful search was made for sperm in the female tract, and although easy enough to find immediately after copulation, they were never detected at a greater period than a week after insemination.

It is not known how widespread the phenomenon of delayed parturition is in marsupials, although many (often verbal) reports are known. A case is cited by Wood Jones⁶ in which a female red kangaroo suckled a pouch young for about a year after the death of the male parent. This female, in captivity in Philadelphia Zoo, could not possibly have mated after the death of the male kangaroo, yet gave birth to another young at about the time the pouch-life of the first young ended. In this, as in other cases of delayed parturition in marsupials, it is interesting to note that the female was lactating during the delayed period. Flynn⁴ recorded several specimens of the macropod marsupial *Bettongia orniculatus* carrying pouch young of widely different ages to have a small blastocyst in one or other uterus. Limited by lack of controlled breeding experiments, he concluded these blastocysts to be stages in normal pregnancy. He was therefore forced to suggest a very short (six weeks) pouch-life of the embryo, since only one young occupies the pouch at one time. In all other macropod marsupials for which information is available, the pouch-life exceeds four months.

I am indebted to Prof. H. Waring for assistance in the field and with surgery, to Mr. A. J. Fraser for making sea transport available and in his capacity of chief warden of fauna in Western Australia, to Miss Nathan for general and histological assistance, and to Mr. Jeapes for animal maintenance. The animal compounds were paid for from an Australian Commonwealth Research grant which also met some of the expenses.

The work reported is part of a programme on marsupial biology under the general direction of Prof. Waring and financed by a grant from the Nuffield Foundation. [Aug. 9.]

Fluorine in Tea and Caries in Rats

FLUORIDATION of communal water supplies is expanding rapidly in the United States, and it has been recommended that water supplies in Britain should also be treated¹. Nevertheless, it is generally recognized that Britons already take appreciable amounts of fluorine in their tea, which is rich in this element. Experiments detailed in this communication deal with the effect of tea infusion on dental caries in the rat.

Litter-mate Wistar rats 23 days of age were used in these experiments, which were continued for sixteen consecutive weeks. The cariogenic diets comprised 800 gm. cracked yellow corn, 30 gm. alfalfa meal, 60 gm. linseed meal, 250 gm. sucrose, 80 gm. corn oil, 50 gm. active dry yeast and 10 gm. sodium chloride; 1 gm. fresh liver was added to this diet once weekly. In the control group, water with 0.02 p.p.m. of fluorine was allowed *ad libitum*. In the experimental group, similar water was used to make strong infusions of a commercial brand of tea (Standard Brands Instant Tenderleaf Tea (orange pekoe and pekoe black)). Such infusions, checked for fluorine concentration by the method of McClelland and Foster², would be considered too strong for humans, who are much more sensitive to fluorine than rats as measured by dental fluorosis. The small content of dextrimaltose in the tea was duplicated in the drinking water of the controls. Repeated periodical comparisons proved that those rats allowed only tea infusions consumed quantities similar to those drinking water. At the end of the experimental period, the animals were weighed and X-ray examinations were made of the skeleton and jaw bones for comparison of calcification and dental caries.

Slightly more than half the original thirty animals in each group were dead at the end of the experiment, leaving eleven pairs of litter-mates for final examination.

Animals in both groups failed to gain weight normally. X-ray examinations showed the skeleton in both groups to be similarly decalcified. Caries of the lower molars with much alveoloclasis was present in both groups with no significant difference (Table 1 and Figs. 1-4).

If fluorine in a concentration of 1 p.p.m. in drinking water is optimum for human consumption as now generally conceded, then it might be expected that strong tea infusions containing 20 p.p.m. of fluorine and taken in large quantities would have some abnormal effect on skeletal calcification. It is recognized that 85 per cent of fluor-

Table 1. EFFECT OF TEA INFUSION ON DENTAL CARIES OF THE RAT

	No. of rats	No. of carious molars	Average wt. at 23 days (gm.)	Average wt. at 185 days (gm.)	Remarks
Control	11	37	83.0	182	Moderate alveoloclasis and skeletal osteoporosis
Tea infusion (20 p.p.m. fluorine)	11	32	84.7	189	Osteoporosis and alveoloclasis similar to controls

ine in dry tea may go into an infusion; but ordinarily brews may contain only 1 p.p.m. of fluorine due to the use of only small amounts of the dried leaf. This may explain the analysis of rib bones among residents of London, England, made by Glock, Lowater and Murray³, who found no greater concentration of fluorine than that found by similar studies in other parts of the world.

The resemblance of dental caries in the rat to that of humans following the consumption of large quantities of tea may be only a coincidence. In order to produce good bone calcification and cario-stasis in the rat, we previously found it necessary to use more than 350 p.p.m. of fluorine, optimum results being obtained with 700 p.p.m. of fluorine when given in the form of Tennessee brown rock phosphate⁴. But there are reports like that of McClure and Mitchell in which as little as 10 p.p.m. of fluorine in the diet of rats was found to have some cario-static effect⁵.

Possibly, the high calcium and phosphorus content of the fertilizer used by us influenced the action of fluorine in the cario-static diets. In humans, toxic doses of fluorine are said to produce osteosclerosis⁶; but whether this precise effect can be observed with dietary insufficiency of calcium and phosphorus, either in experimental animals or man, has not been established. Besides considering other factors such as solubility and absorbability of fluorine from tea infusions, it will be interesting to observe whether in Great Britain the same good results with fluoridation of communal water supplies can be obtained as in the

Fluorine Content of some Nigerian Waters

FLUORINE absorption from drinking water during the period of calcification of the teeth has long been correlated with mottling of the dental enamel¹. In East Africa the excessive amounts of fluorine in some drinking waters have become a matter for urgent consideration²; but little is known of fluorine distribution in West African waters.

The surface rocks of Nigeria consist of two large areas of granites separated by marine sediments in the Niger and Benue valleys; Tertiary sediments occur in the north-east in the Lake Chad drainage basin.

On the Central Plateau, a series of Younger granites are known to have a high fluorine content which does not, except in very small amounts, break down into compounds soluble in water; fairly extensive parts of these granites are covered by basaltic lava flows of Tertiary and Recent age. Streams used for drinking-water arise by seepage from below the basalt or by drainage off purely granitic areas. Ten samples of representative Plateau waters were flown to Great Britain for examination; in nine instances the fluorine content was low—between 0.2 and 0.4 parts per million—and in one sample there was no fluorine. A mild degree of dental fluorosis was seen among members of six aboriginal tribes who lived on the Plateau.

Fluorine occurs among the minerals present in the Niger and Benue valleys. A sample of water from the shaft of a lead-zinc lode near Abakaliki contained 3.3 p.p.m. of fluorine; but surface waters in general would contain considerably less: of 65 primary schoolgirls aged seven to fifteen years examined in Niger Province, eight showed mottled dental enamel. Dental fluorosis was seen in the teeth of adults whose homes were in Adamawa, Bauchi, and Bornu Provinces. It is probable that the sources of fluorine in these areas are the crystalline rocks of the basement complex. Six samples of well water from Maiduguri town, in Bornu, had fluorine contents ranging from 0.1 to 1.2 p.p.m., and 15.8 per cent of thirty-eight girls in boarding school had a moderate degree of mottled enamel.

It is concluded that in Nigeria the fluorine compounds present in Pre-Cambrian rocks do not, except in small amounts, become soluble in drinking waters.

Samples of water were obtained for examination with the help of Dr. R. Jacobson, Mr. W. N. MacLeod and Dr. A. M. J. de Swardt, of the Geological Survey of Nigeria. Thanks are due to Prof. Margaret Murray, who undertook the examination of Nigerian waters for their fluorine content.

Enzymic Iodination of Milk Proteins

RECENTLY, Pitney and Russell Fraser¹ have reported studies in which they utilized, as a model system for antithyroid drug evaluation, a procedure based on that of Keeton² for the enzymic iodination of milk proteins. This has prompted us to outline some of our observations with a similar system using purified milk enzymes and proteins. Native casein in a finely suspensible form was obtained from separated milk by differential high-speed centrifugation at 0°. It was washed with water and freeze-dried from an aqueous dispersion. β -Lactoglobulin was prepared essentially according to Palmer³. In order to obtain lactoperoxidase (of about 40 per cent purity as judged by absorption data) the fraction of milk separating at 50–70 per cent saturation with ammonium sulphate was treated by an unpublished procedure developed by Dr. D. Morell, who also kindly provided a purified specimen of xanthine oxidase⁴.

In order to test their relative reactivity in iodination experiments, the purified proteins (150 mgm.) were shaken and incubated in duplicate for 1 hr. at 37° in 0.05 M phosphate buffer medium at pH 6.8 with added xanthine (600 μ gm.), iodine-131 (usually 50 μ c.) with carrier potassium iodide (15 μ gm.) and the two enzymes (in amounts equivalent to ten times the average contents of milk, based on the casein used), the final volume being approximately 5 ml. The precipitates obtained with 10 per cent trichloroacetic acid were washed twice with 5 per cent trichloroacetic acid, hydrolysed with 2 N sodium hydroxide for 16 hr. at 105°, and the hydrolysates extracted twice with equal volumes of *n*-butanol. The butanol extracts were washed twice with equal volumes of 4 N sodium hydroxide/5 per cent sodium carbonate. Although counts were made on the several fractions, only the radioactivity contents of the washed butanol extracts are given in Table 1 (A). Under these conditions, our best results indicated about 2 per cent binding of iodine in the butanol-soluble ('thyroxine') form by casein. Chromatographic fractionation of both alkaline and enzymic hydrolysates (using purified thyroid protease⁵ as the enzyme) showed that more than 90 per cent of the iodine incorporated was fixed in the form 3-iodotyrosine. The addition of cupric ions and tyrosine as recommended by Weiss⁶ in his iodine-uptake studies using particulate components of thyroid tissue gave no increase in the butanol-soluble fraction (Table 1, D).

Purified β -lactoglobulin exhibited a very weak capacity for binding iodine in butanol-soluble form.

Table 1

	A		B				C		D	
	Cas.	Lg.	Cas.	Lg.	Cas.	Lg.	Cas.	Lg.	Cas.	Cas.
Butanol extract (μ C.)	4.45	2.82	2.14	0.73	1.82	0.99	2.00	1.57	4.00	4.58
After first treatment with alkali (μ C.)	1.80	0.18	0.67	0.04	0.43	0.03	0.59	0.06	1.29	1.33
After second treatment with alkali (μ C.)	1.03	0.03	0.52	0.015	0.37	0.01	0.45	0.03	0.82	0.81
Ratio: Cas./Lg.	34	1	35	1	37	1	15	1	—	—

A. Casein (Cas.) and lactoglobulin (Lg.) each 150 mgm., incubated 1 hr., 37°, under standard conditions and then hydrolysed (see text).

B. General conditions as in A, but Cas. and Lg. mixed prior to, and Cas. and Lg. subsequent to, incubation. Iodinated proteins separated by precipitation at pH 4.6 (Cas.), then with trichloroacetic acid (Lg.), before hydrolysis.

C. General conditions as in A, but with the following additions before incubation: to Lg. 5 ml. milk supernatant, from which casein was removed by high-speed centrifuging; to Cas. 5 ml. phosphate buffer.

D. General conditions as in A, but with addition of cupric ions and tyrosine (each $1.8 \times 10^{-4} M$) to Cas.

Even allowing for its lower tyrosine percentage composition (3.78) than casein (6.1)*, it is much less efficient under the conditions used. In order to ascertain whether the purified casein contained, by contrast, an activator of the reaction, equal amounts of β -lactoglobulin and casein test solutions were mixed immediately before, and following, the incubation period, and the solutions then fractionally precipitated (casein at pH 4.6, β -lactoglobulin with trichloroacetic acid). Table 1, B shows that the results were comparable. To examine this point further, the supernatant of milk (5 ml.), from which the casein had been removed by prolonged high-speed centrifugation, was added to a β -lactoglobulin test solution prior to incubation. It is possible that the apparently slight favourable effect (decrease in the ratio casein to lactoglobulin) observed (Table 1, C) may have been due to traces of casein in the milk supernatant added.

From our overall results it seems that the tyrosine residues in β -lactoglobulin are not as favourably situated for conjugation to the iodinated thyronines as are those in casein, and that, in the iodination of

milk, casein would be almost entirely responsible for the butanol-soluble fraction.

Keston⁸ showed that thiourea is an effective inhibitor of the uptake of iodine by the proteins of milk, similar findings being obtained by Pitney and Russell Fraser¹ for both 2-thiouracil and resorcinol in the enzymic iodination of casein. However, the latter authors failed to prevent iodination of casein with thiouracil, in contrast to resorcinol (60 per cent inhibition), under enzyme-free conditions in which the conversion of iodide to iodine was brought about by incorporating dilute hydrogen peroxide in the medium. They therefore conclude that such anti-thyroid drugs do not act by removal of available free iodine⁹. However, the failure of thiouracil to inhibit in the 'chemical' system could be due to its greater sensitivity towards dilute peroxide than resorcinol. In fact, we have shown that thiouracil, unlike resorcinol, is completely changed by added peroxide under conditions comparable to those used by the authors mentioned, whereas it survives to a large extent when the peroxide is produced enzymically.

Solutions of thiouracil ($10^{-3} M$; 100 ml.) with and without hydrogen peroxide ($10^{-3} M$) were incubated for 45 min. at 37° and then frozen and dried in this condition. The residues were dissolved in warm *n*-butanol (saturated with water), applied to paper and run in *n*-butanol/water (16 hr.). As can be seen from the photograph of the chromatogram taken with ultra-violet light¹⁰ the thiouracil spot has shifted as the result of peroxide treatment (Fig. 1, A). Spraying the paper with Chargaff's reagent (iodine and sodium azide) produced an immediate reaction with the control spot, whereas the other reacted only weakly after some minutes. Such differentiation is similar to that observed with cysteine and cystine respectively¹¹. The chromatogram (*n*-butanol/acetic/water¹²; Ehrlich reagent spray¹³) obtained after resorcinol had been treated under identical conditions is illustrated in Fig. 1, C. The control and treated spots are comparable in appearance and position; this was also the case when the chromatogram was run in *n*-butanol/ammonia.

The effect on thiouracil of peroxide produced enzymically was tested by incubating, for 45 min. at 37°, a solution of thiouracil ($10^{-3} M$; 100 ml.) containing xanthine (4.5 mgm.) and excess lactoperoxidase and xanthine oxidase, so that the system gave a strong positive reaction with Nadi reagent. Xanthine was omitted from the control. The incubated solutions were then treated as for the chemical system. As can be seen from Fig. 1, B, a major proportion of the thiouracil remains unchanged under these conditions.

Fig. 1. Chromatograms of peroxide-treated anti-thyroid drugs. A. (i) Thiouracil ($10^{-3} M$) incubated for 45 min. at 37° with hydrogen peroxide ($10^{-3} M$). (ii) Thiouracil control—no peroxide added. Solvent system *n*-butanol/water.

B. (i) Thiouracil control—no xanthine added. (ii) Thiouracil ($10^{-3} M$) incubated for 45 min. at 37° with xanthine and excess xanthine oxidase and lactoperoxidase. Note trace of oxidation product at lower R_F. Solvent system *n*-butanol/water.

C. (i) Resorcinol ($10^{-3} M$) incubated for 45 min. at 37° with hydrogen peroxide ($10^{-3} M$). (ii) Resorcinol control—no peroxide added. Solvent system *n*-butanol/acetic/water.

Induction of Ovarian Tumours with 9 : 10-Dimethyl-1 : 2-Benzanthracene

MAMMARY carcinoma can be readily induced in certain strains of mice by treatment with 20-methylcholanthrene. In the course of experiments intended to investigate whether other members of the same group of carcinogenic hydrocarbons are also effective on the breast, an incidental finding has been made that treatment with 9 : 10-dimethyl-1 : 2-benzanthracene leads to the appearance of ovarian tumours.

Female mice of the Bonser *IF* strain were treated with 0.5 per cent 9 : 10-dimethyl-1 : 2-benzanthracene in olive oil by the technique previously described¹. After a small pilot series to determine dosage, the first batch consisted of thirty animals, of which eight other mice survived when the first ovarian tumour was observed after 238 days; of these, one further mouse revealed a macroscopic ovarian tumour and others showed microscopical abnormalities. In a second series of twenty-nine animals, the first ovarian tumour was found at 196 days, when there were twenty-two survivors. Of these, nine were afterwards found to have macroscopic ovarian tumours, and four showed early tumours histologically. Of the total thirty-one mice 'at risk', there were therefore macroscopic tumours in eleven (35 per cent), and the total tumours found were fifteen (48 per cent).

The macroscopic tumours were 0.5-1 cm. in diameter, bright yellow in colour and sometimes haemorrhagic. Histologically, they were all of obviously granulosa-celled origin. Apart from the tumours, all the ovaries of mice surviving to tumour age showed histological abnormalities. One of the tumours has been successfully transplanted. It retains its histological differentiation. Some at least of the tumours appear to function oestrogenically, as estimated by vaginal smears; the non-tumour-bearing animals tested have, on the other hand, been in continuous di-oestrus. Most of the animals, including all those with ovarian tumours, have also showed breast carcinomata. There is a suggestion

that the average number of breasts affected is greater in the ovarian-tumour mice than in the others.

Ovarian tumours have not been obtained in C57 black mice with 9 : 10-dimethyl-1 : 2-benzanthracene. It has been confirmed by *ad hoc* experimentation that methylcholanthrene does not give ovarian tumours in the *IF* strain, and does not lead to histological abnormalities of the extent found following dimethyl-benzanthracene treatment.

Further work is in progress before the results are published in detail, but we feel justified at this stage in directing attention to what must be regarded as an important qualitative difference in the biological action of two carcinogens belonging to the same general group of cyclic hydrocarbons.

Influence of the Thyroid upon the Survival-Rate of Guinea Pigs treated with X-Rays

It has been shown that the lesions of the thymus induced by X-rays are restored more quickly in thyroidectomized guinea pigs than in normal animals. This supported the supposition that (to a certain extent) disorders induced by X-rays may be dependent upon the thyroid.

The influence of X-ray irradiation upon the thyroid is still under discussion¹. This is understandable, since it can be shown that lethal irradiation does not induce any sign of thyroid stimulation in rats, whereas signs of thyroid stimulation are observed after a non-lethal dose of radiation².

A total of 46 male guinea pigs of average weight 200 ± 15 gm. were irradiated and divided into three groups: (1) 15 thyroidectomized animals; (2) 16 thyroidectomized animals, which received every second day injections of 6 γ thyroxin per 100 gm. (this is sufficient to prevent the thymus atrophy determined by thyroid extirpation³); (3) 15 normal controls.

The animals were irradiated under the following conditions: one single total irradiation of 800 r., given with a Siemens-Halske apparatus, 160 kV., 10 mamp., target distance 50 cm., field 20 cm. $\times$ 24 cm., 1 mm. copper filter. Thyroidectomized animals were irradiated fifteen days after the operation. The survival-rate of these animals is shown in Table 1.

Table 1. SURVIVAL-RATE OF GUINEA PIGS FOLLOWING A SINGLE TOTAL X-RAY IRRADIATION OF 800 R.

Days after irradiation	Survival-rate		
	Normal	Thyroid-ectomized	Thyroidectomized and injected with thyroxin (6 γ per 100 gm. and 48 hr.)
0	15	15	16
8	15	15	16
9	13	14	15
10	11	10	13
11	8	8	8
12	6	5	6
13	5	4	5
14	4	4	4
15	3	3	3
16	3	3	3
20	3	3	3

It is obvious that thyroidectomy has not shown any influence upon the resistance of guinea pigs to X-rays. The survival curve in thyroidectomized guinea pigs is almost the same as in normal animals. This was also confirmed in thyroidectomized animals injected with thyroxin in physiological amounts.

This result seems to be in contradiction to the previous observations, from which it was concluded that lesions of the thymus induced by X-rays may be to a certain extent the expression of thyroid stimulation occurring in these conditions. In spite of this, thyroid stimulation is observed after non-lethal irradiation only¹. It seems, therefore, that there is an upper limit to thyroid stimulation. Certainly, the part played by the thyroid in disorders induced by X-rays can be considered as slight.

Histochemographical Effect in Rat Kidneys

In 1949, Boyd and Board¹ showed that tissue specimens placed in contact with the emulsion of a photographic plate stored in the dark affected the emulsion in such a way that images of the specimens were obtained following development and fixing. These images, due to chemical action of the specimen on the emulsion, were termed histochemographs.

Histochemographs of various tissues from normal and tumour-bearing albino rats (14 day-old transplants of dibenzanthracene sarcoma (Rd/3), Walker carcinoma and a 20-methylcholanthrene-induced tumour) have now been compared. The transplant animals were obtained from the University of Sheffield Field Laboratories and, in the first experiments, normal rats from the University of Sheffield Animal House were used. Blood, spleen, pancreas and liver preparations from these groups did not differ markedly; but a striking difference appeared in kidney histochemographs prepared as follows.

Rats under ether anaesthesia were sacrificed by exsanguination (aorta severed). Without delay, the kidneys were removed, sliced longitudinally and the halves blotted with Whatman No. 50 filter paper. The halves were placed (cut-side downwards) on the emulsion side of Ilford photographic paper (Contact; 03.1P; single weight; hard glossy) and the preparation mounted on a 'Pliofilm'-covered cork mat under 'Wratten Red Safelight' in a dark room. The preparation (generally kidneys from three normal and three tumour animals were compared simultaneously) was stored in a light-tight box at -15°C . for 50 hr. Then the film was washed for 3 min. in running water to remove tissues, developed five minutes in Kodak document developer at 20°C ., washed and fixed.

As illustrated by the accompanying photograph, prepared from an original histochemograph by printing on Kodak Autopositive Document Paper, kidney preparations from thirteen tumour animals each showed a marked brown crescent (A) in the cortex-

medulla zone. This effect was absent in the kidneys of all but two of fifteen normal rats which gave more or less uniform pale grey histochemographs (B). However, when the kidneys of normal rats from the University Field Laboratory stock were examined, a high proportion of these were found to give the brown crescent reaction (see table). Thus the brown crescent reaction could not be attributed to the presence of a tumour as was at first supposed.

Animals	Brown crescent reaction	
	+	-
17 tumour rats (Univ. Field Lab.)	13	4
17 normal rats (Univ. Field Lab.)	14	3
15 normal rats (Univ. Animal House)	2	13

Rats from the University Field Laboratory are of the Wistar strain bred there. They are maintained on bread and milk (no water) with supplements of horse meat and cod liver oil separately every second and third day. On the other hand, rats from the University Animal House were obtained or bred from Wistar strains received from dealers. These animals were maintained on commercial rat cubes (Edinburgh Rat Cube No. 86). It has not been possible to examine completely the effect of diets on the kidney reaction; but some tumour animals maintained for several days on Diet No. 86 and water still gave the brown crescent reaction. The histochemographical effect was found in both male and female tumour and normal rats.

Perhaps we are dealing with a strain difference or with the effect of a disease prevalent in the Field Laboratory animals. Sections from kidneys which gave a positive reaction were not histologically abnormal, and no amyloid could be detected in them. The substance responsible for the brown crescent reaction appears to be susceptible to decomposition or to be readily diffusible, since kidneys which have given a positive reaction are no longer capable of producing the effect after 50 hr. exposure.

Thanks are due to Mr. O. Thornburn of the University of Sheffield Field Laboratories for supplying the tumour animals, to Dr. H. E. Harding for examining the histological preparations, and to Prof. H. N. Green for his interest. The work was supported by a grant from the British Empire Cancer Campaign.

High Resolution Electron Micrographs of Thin Tissue Sections

Using a method described elsewhere¹, we have been able to cut serial sections of about 250 Å. thickness, and, by varying the speed of cutting successive sections, serial sections of thickness alternately about 350 Å. and 150 Å. There were always thin and thick areas within individual sections. On the basis of the general rule suggested by Cozzetti², that the optimum resolution obtainable from a section is of the order of one-tenth of the thickness, the thinner parts of the 150 Å. sections should afford resolutions of 10 Å. We have succeeded in obtaining such resolutions, as illustrated in Fig. 1.

The specimen is a section of a C3H mouse breast tumour; an intracellular 'double membrane' is clearly visible across the centre of the picture. Comparison of the detail observed with the 100 Å. scale shows that resolutions of 10 Å. have been obtained.

It is clearly necessary to avoid mistaking photographic grain for fine detail. For this reason, the following controls were used. First, the negatives and prints at all stages were submitted to several of the leading photographers here. All were of the opinion, without any doubt, that the detail observed did not represent photographic grain. Secondly, a negative similar so far as possible and particularly in emulsion, development, etc. (actually the next field on the same plate), to the one shown here, but electronically slightly out of focus, was put through a similar process of enlargement; sharp optical focusing was obtained by the use of a small scratch in the emulsion. In such a print no sign of detail

C3H mouse breast tumour. Intracellular 'double membrane' (1) in focus; (2) out of focus

is visible (Fig. 2), indicating that the structure shown in Fig. 1 represents neither photographic grain nor an artefact due to electron scattering in the emulsion.

While resolution of this order is thus shown to be attainable in electron micrographs of sections of animal tissues, at present it can only be attained with selected fields.

Thanks are due to Mr. J. B. Kirkham, of the Department of Experimental Pathology and Cancer Research, for the photographic enlargements.

Fructose in the Foetal Fluids of Deer

The foetal fluids of a number of species have been examined recently for the presence of free fructose¹. This study has now been extended to the examination of the foetal fluids of three species of deer. The fluids were obtained after pregnant does had been shot. Protein-free filtrates of the fluids were prepared by the barium-zinc method of Somogyi². Total reducing substances were determined by the method of Nelson³, and fructose by a modification of the Seliwanoff method due to Cole (as described by Bacon and Bell⁴).

Fructose was shown to be present in both the allantoic and amniotic fluids of three roe deer (*Capreolus capreolus*), one Père David's deer (*Elaphurus davidianus*) and many specimens of fallow deer (*Dama dama*). The fructose concentrations were usually within the range 100–300 mgm. per cent, and accounted for a large proportion of the total reducing substances. The concentrations of both total reducing substances and fructose were invariably higher in the allantoic than the amniotic fluid. The non-fructose reducing substances consisted mainly of glucose.

Sufficient specimens of foetal fluids of fallow deer became available for a study of the variation of the sugar concentrations with foetal age. Fig. 1 shows the variation of total reducing substances and of fructose in the allantoic fluids and of total reducing substances in the amniotic fluids with foetal crown-

Fig. 1

rump length. Fructose is the major constituent of the amniotic total reducing substances. The foetal ages extend over the period 80-130 days (gestation period approximately 230 days). Unfortunately, no specimens of foetal fluids were available from near-term fetuses.

The results lead to the following conclusions. The concentrations of both fructose and glucose in the allantoic fluid were higher than in the respective amniotic fluid. High concentrations of the sugars in both fluids occurred at a very early stage of pregnancy, and lower values were recorded as the foetal length increased. These results must be considered together with the fact that the volumes of the foetal fluids increase during pregnancy*. The results reported here show greater consistency and a somewhat different type of behaviour from those recorded on the foetal fluids of sheep*. It has not been possible, as yet, to compare the composition of the foetal fluids with that of foetal blood.

I am grateful to Dr. R. J. Harrison, of the Department of Anatomy, who supplied the specimens of foetal fluids, to Prof. F. L. Warren for advice, and to the Sir Halley Stewart Trustees for a grant.

Detection of the Sex of Cat Embryos from Nuclear Morphology in the Embryonic Membrane

A sex difference in the morphology of intermitotic nuclei has been described in the nervous system¹ and various tissues and organs of the mature cat². Nuclei of females contain a special mass of chromatin, the sex chromatin, which is seldom seen in nuclei of males. Evidence available so far suggests that the sex chromatin of females represents heterochromatic portions of the two X chromosomes.

It has been found that the sex of cat embryos can be detected by examining nuclei in whole mounts of the embryonic membranes. In addition to the theoretical interest of this observation, the method may prove useful in studies which require a decision as to the sex of embryos before the genitalia have developed distinctive sex characteristics.

The embryonic membrane (fused amnion and allantois) was studied in thirty-nine embryos from ten litters of 19-50 days gestation. The membrane was fixed in a

formol-acetic-alcohol mixture for 24 hr. and in 70 per cent alcohol for a further 24 hr. Small pieces were removed from thin parts of the membrane between blood vessels, and placed in distilled water in watch-glasses. Separate pieces of embryonic membrane from each embryo were stained with Harris's hematoxylin and cresyl echt violet, the solutions being changed with a pipette. The stained preparations were transferred to a microscope slide, cleared with xylol, mounted in piccolyte, and studied with the oil-immersion objective.

Nineteen of the thirty-nine embryos were sufficiently mature to permit identification of sex by examination of the external genitalia; eleven were females and eight were males. The nuclei of the amnion and allantois had the following characteristics in these nineteen embryos: 96-98 per cent of the nuclei in females showed a mass of chromatin, plano-convex in shape, lying at the nuclear membrane (Fig. 1). A similar, although smaller, mass of chromatin was seen in only 7-12 per cent of nuclei in the embryonic membrane of male embryos (Fig. 2). The special mass of chromatin which is characterized by a size relation to sex is the sex chromatin, as described earlier in tissues of adult cats³.

Twenty embryos were in an earlier stage of development, prior to differentiation of the external genitalia. Nuclei of the amnion and allantois showed a typical female morphology in eleven embryos, the sex chromatin being identified in 96-100 per cent of nuclei. The morphology of the nuclei was typically male in the other nine embryos, with a small mass which might be interpreted as sex chromatin visible in 8-9 per cent of nuclei. It is inferred that these two groups of early embryos were female and male, respectively.

Nuclear morphology within the embryo was similar to that of the embryonic membrane. A detailed account of the sex difference in the morphology of the nucleus in embryonic tissues is in preparation.

It is possible that a sex difference in the intermitotic nuclei of amnion and allantois, and in embryonic tissues generally, may occur in those animals which have a sex difference in the nuclei of mature nerve cells⁴, although embryos of species other than the cat have yet to be studied from this point of view.

Fig. 1. Nuclei in the embryonic membrane of a female cat embryo. They contain a mass of sex chromatin which lies at the nuclear membrane in most instances.

Fig. 2. Nuclei in the embryonic membrane of a male cat embryo. A chromatin mass, comparable in size, shape and position with the sex chromatin of the female, is seldom seen in male nuclei.

This work was made possible by a grant-in-aid from the National Research Council of Canada.

Influence of Position of Truss on Pleiocotyly in Tomato

LEWIS¹ has shown that position of truss affects the manifestation of rogues in tomato. Darlington and Mather² believe this character is plasmagenically inherited, like other forms of rogues in inbreeding species. An investigation was therefore made to determine whether truss position and plasmagenes also influence pleiocotyly, that is, the variation in cotyledon number, in tomato (*Lycopersicon esculentum*).

Eight plants of Clucas-99 variety were used, and fruits were harvested from individual trusses. Seeds from each were sown. Fig. 1 gives the mean amount of pleiocotyly occurring in offspring from all plants plotted against truss position. This shows that there is a decrease in pleiocotyly from the first to the third truss, with a rise at the fourth. This is converse to that for roguing and truss position found by Lewis¹. An analysis of variance shows that $P = 0.01$ for 'trusses' and $P > 0.20$ for 'plants'. Hence, truss position is important in effecting manifestation of pleiocotyly in the offspring; but plants do not differ significantly from one another in their effects, which is not unexpected in an inbred.

As the data strongly indicate that truss position influences pleiocotyly production, and because rogues in tomatoes are possibly plasmagenically controlled, a test was made to see whether rogues and pleiocotyly are associated. One might expect that rogues would produce more pleiocotyly than normal plants if pleiocotyly were influenced by cytoplasmic factors. Table 1 gives data from Clucas-99. A χ^2 analysis for independence gives $\chi^2 = 1.53$ and $P > 0.20$. Hence roguing and pleiocotyly are independent of each other; however, pleiocotyly produce twice as many rogues. This provides further evidence that cytoplasmic effects are not primarily responsible for the production of pleiocotyly, but might play some part in their activities.

Fig. 1. Per cent pleiocotyly frequency in Clucas-99 tomato variety plotted against position of truss (lowest is 1, highest is 4). Each spot represents the mean of eight plants.

Table 1. DISTRIBUTION OF PLEIOCOTYLY IN NORMAL AND ROGUE CLUCAS-99 TOMATO

Type of pleiocotyly	Normal seedlings	Rogue seedlings
Monocot.	1	0
Dicot.	27	7
Dicot.-abnormal	2	1
Pseudo-tricot.	4	1
Tricot.	9	7
Pseudo-tetracot.	2	1
Tetracot.	1	0
Total	46	17

Table 2. PLEIOCOTYLY IN STONER'S EXHIBITION TOMATO

Cross	Dicot. (per cent)	Pleiocot. (per cent)	No. of rogues
Normal selfed	100	0	0
Rogue $\times$ normal	96	4	0
Normal $\times$ rogue	98	7	1 pleiocot.

Data were also available for Stoner's Exhibition variety. Dr. D. Lewis (unpublished) has found the distribution of pleiocotyly as given in Table 2. Here again pleiocotyly were not rogues; but pleiocotyly increased in proportion following reciprocal crosses between rogues and normal. This suggests that dicotyly is a condition partly resulting from balance between chromosomes and cytoplasm. When one or other is disturbed, the threshold for dicotyly is broken down and pleiocotyly results.

Some Polyenes from *Brassica rutabaga*

ROBERT studies on fruit and vegetable processing have shown some natural constituents of the material to be very sensitive to treatments, particularly heat. In the course of dehydration experiments with roots of *Brassica rutabaga*, the pigmentation of the tissues has been examined in detail.

Extraction of the pigment was carried out in the dark by means of a low-temperature technique¹, and subsequent chromatographic analysis of the solution on an alumina column yielded several polyenes adsorbed less strongly than all-*trans*-lycopene. Their absorption spectra after repeated chromatography showed single absorption maxima in the region 420-450 m μ with no fine structure, and all except No. 5 failed to agree with known maxima either for naturally occurring poly-*cis*-compounds^{2,3} or for poly-*cis*-compounds derived from the isomerization of polyycopene⁴. These differences cannot easily be explained by variations in solvent and spectrophotometer. In each case it was possible to obtain all-*trans*-lycopene from the solution of chromatographically pure pigment by isomerization with iodine⁵. These pigments are, therefore, hitherto uncharacterized poly-*cis*-lycopenes. Pigment No. 5 showed a close resemblance to poly-*cis*-lycopene IV isolated from pyracantha berries by Zeiselmeister⁶.

We believe that these pigments should have a more distinctive numbering than that referring to their position on an adsorption column, and make the following proposal, namely, that the figure for

ABSORPTION MAXIMA OF SOME OF THE PIGMENTS ISOLATED FROM *Brassica rutabaga*

Development sequence on alumina column	Absorption maxima in petroleum ether ¹ boiling point, 60–80° C.		Identity of pigment

* Regions of inflexion

the main absorption maxima in the region 400–500 mμ in petrol ether of boiling point 60–80° C., deleting the first numeral, be placed after the words poly-*cis*-lycopene. For example, the poly-*cis*-lycopene with its absorption maximum at 429 mμ would become 'poly-*cis*-lycopene 29'.

Of particular interest is pigment No. 2 with a maximum at 418 mμ. This is the shortest wavelength maximum yet recorded for any lycopene isomer, and its position does not concur with present theories for spectral displacements for *cis* bonds by which all-*cis*-lycopene would be expected* to have its maximum in the region of 430 mμ.

Other polyenes identified in this group of pigments were zeta-carotene, beta-carotene, and a group of yellow fluorescent compounds.

some cases, but we wish to record very briefly some of our observations on the living male germ cells of the grasshopper *Chrotogonus* sp. and the common house cricket *Gryllus domesticus* made under the phase-contrast microscope, after studying the spermatogenesis of these two insects by the normal laboratory technique of fixing and staining.

We have seen very clearly in the living cells not only the mitochondria, the Golgi elements, the chromosomes even in resting cells, and the acrosomal vesicle with the acrosomal granule dancing within it, but also the spindle fibres and the mid-body granules.

Out of scores of figures recording these observations, we have selected only two. Fig. 1 represents the late telophase II of *Chrotogonus* sp. The nucleus (N) of the secondary spermatocyte has already divided into two; and the spindle fibres with the mid-body granules (M.B.) at their equator and the filamentous mitochondria (M) at their two poles can be very clearly made out. The Golgi elements exist at this stage in the form of vesicles (G) spread out uniformly in the cell. Fig. 2 represents an early spermatid of *Gryllus domesticus*. At AV is shown the acrosomal vesicle with its contained acrosomal granule; at N is the nucleus; and at M.N. lies the mitochondrial nebenkern.

Are Spindle Fibres and Mid-body Granules Artefacts?

In consonance with the colloidal conception of protoplasm, it is generally believed that the fibres and the mid-body granules of the mitotic spindle are coagulation effects and are not an image of reality. The spindle is conceived as a fusiform area of protoplasm having high viscosity. This may be true in

Selective Absorption of Optical Antipodes by Proteins

We wish to report the resolution of α-methoxyphenylacetic acid on wool, the (+)-form of the acid combining preferentially, when wool is immersed in a dilute aqueous alcoholic solution of the (±)-acid at the room temperature.

In previous communications¹⁻³ we have shown that mandelic acid and many of its derivatives carrying simple nuclear substituents, and several analogous acids derived from larger aromatic nuclei, such as naphthalene, anthracene and diphenylene oxide, are resolved without difficulty on wool. In all these instances, the acids carried hydroxyl groups, and there was the possibility that the difference in the

degree of absorption of the two forms of the anion was due to a difference in the extent of the interaction of their hydroxyl groups with the protein.

Our present result shows that the occurrence of resolution is not restricted to the hydroxy acids. Indeed, the degrees of resolution of α -methoxyphenylacetic acid and mandelic acid are of the same order under the same conditions.

The α -methoxyphenylacetic acid used in our experiments was prepared by Reeve and Christoffel's method⁴; it melted at 70° (literature: m.p., 70.5–71°). Wool (30 gm.) was immersed in a solution of the ($\pm$)-acid in 500 c.c. of a mixture of equal volumes of water and alcohol, and after a time the amounts of the acid absorbed and not absorbed, and the rotations of the two fractions, were determined.

	Exp. 1	Exp. 2
Initial weight of acid in solution	7.31 gm.	7.83 gm.
Period of immersion	18 hr.	24 hr.
Weight of acid absorbed	2.54 gm.	2.45 gm.
Weight of acid unabsorbed	4.76 gm.	5.38 gm.
Rotation of acid absorbed	+ 0.19°	+ 0.20°
Rotation of acid unabsorbed	- 0.19°	- 0.20°

The rotations were measured in a 2 dm. tube in a Hilger model, Type M 413, polarimeter, each of the two fractions being dissolved in 17.5 c.c. of alcohol. They are of the same order as those obtained with mandelic acid⁵ in similar circumstances, and if the molecular rotations of the two acids do not differ greatly it would follow that mandelic acid and its methyl ether are resolved to almost the same degree; $[\alpha]_D$: (–)-mandelic acid, –159.73°, in water⁶; (+)-mandelic acid, +156.40°, in water⁶; (–)- α -methoxyphenylacetic acid, –165.8°, in water⁷; (+)- α -methoxyphenylacetic acid, probably not optically pure, +54°, in alcohol⁸.

It is now possible to recognize some of the factors which enable the resolution of acids on proteins to be demonstrated. The protein itself must carry an adequate number of basic groups. Thus, resolution of mandelic acid has been shown to occur on wool and casein but not on silk^{1,2}. The molecular rotation of the acid should be high, for the degree of separation of the optical antipodes so far observed is small. The acid should not contain groupings which favour the non-specific absorption of its anions by non-ionic forces. Thus, whereas *p*-methoxy, *p*-ethoxy, *p*-pentoxy and *p*-heptoxy mandelic acids are resolved without difficulty on wool, *p*-hexadecoxymandelic acid is not resolved at all⁹. Similarly, many acids containing azo-groups are not resolved on wool^{10,11}.

The resolution of acids on proteins and the extent to which it occurs is of considerable interest for the theory of biochemical processes. It has always appeared feasible that the difference in behaviour of the optical antipodes of the α -amino-acids, the α -hydroxy acids and other acids in natural processes could be related to the preferential absorption of one or other of the two enantiomorphs. Our results do not support this view; for although we have demonstrated the resolution of acids on proteins, the degree of resolution has always been small and insufficient to account for the striking differences in biochemical properties which are often observed, unless the degree of separation can be increased in natural

processes, as by continued resolution at a succession of surfaces.

Carcinogenic Azo-compounds

In 1940, Cook *et al.*¹ reported that 2:2'-azo-naphthalene (I) produces cancers of the liver in mice. The compound was also given to rats by subcutaneous injection, and with the food; but in this species no neoplastic changes were found in the livers. There is a brief note in the 24th Annual Report of the British Empire Cancer Campaign, 1947, p. 147, that a few small areas of cholangiectasis were observed in three out of eighteen rats receiving this compound by the oral route. No further details have been published, but Dr. A. H. M. Kirby has kindly informed us (see Kirby, Ph.D. thesis, London, 1949) that he obtained a number of foci of hepatoma in rats surviving more than 500 days. These rats were maintained on a balanced diet and were given the azonaphthalene orally. This behaviour is in marked contrast to 4-dimethylaminoozobenzene (II, X = H), which is a liver carcinogen in rats, but which is very much less active in mice. However, 4-dimethylaminoozobenzene is only effective as a liver carcinogen when tested in rats which are maintained on a diet that is low in protein and in riboflavin², and the original experiments with 2:2'-azonaphthalene were completed before the importance of the diet had been established. It therefore seemed of interest to re-test 2:2'-azonaphthalene for carcinogenic activity in rats maintained on a suitably restricted diet, for direct comparison with 4-dimethylaminoozobenzene. At the same time, an opportunity has been taken to test other azo-compounds which are also of interest in the study of the relationship between chemical constitution and carcinogenic activity³.

(I)

(II)

(III)

All experiments were carried out with batches of ten Wistar hooded rats, which were given food and water *ad lib*. The diet was similar to Kirby's R.D. 3⁴, except that white flour was used instead of rice starch. Control rats lost weight when maintained on this diet; but no abnormalities could be detected in the livers of animals killed after six months. To

Compound	Tumours Survivors	Relative carcinogenic activity (ref. 3)
2:2'-Azonaphthalene (I)	0/9	0
1-Benzeneazobenzene	0/8	0
2-Benzeneazobenzene	0/6	0
4-Dimethylaminoazobenzene (II, X = H)	7/7 8/8	++
4:4'-Di(dimethylamino)azobenzene (II, X = NMe ₂)	0/8	0
4'-Methoxy-4-dimethylaminoazobenzene (II, X = OMe)	4/10	+
4-Methoxyazobenzene (III, Y = OMe, X = H)	0/7	0
4:4'-Dimethoxyazobenzene (III, X = Y = OMe)	0/8	0

establish the effectiveness of this restricted diet, and to enable comparisons of relative carcinogenic potency to be made with other workers⁴, two groups of rats were given the diet to which 4-dimethylaminoazobenzene had been added at a level of 0.08 per cent. The surviving rats were sacrificed after six months, and tumours were observed in all the livers and confirmed by histological examination (see table). Other workers have also obtained a 100 per cent incidence of liver tumours with this compound when tested under somewhat similar conditions⁴.

When tested under the same conditions at the same dose-level (on a molecular weight basis), 1-phenylazonaphthalene and 2-phenylazonaphthalene proved to be inactive. 2:2'-Azonaphthalene was similarly ineffective, no abnormalities being observed in the livers of any of the surviving animals. It can only be concluded, therefore, that 2:2'-azonaphthalene has little or no carcinogenic activity in the rat, when tested under conditions in which 4-dimethylaminoazobenzene is a very effective carcinogen.

It has been suggested¹ that, in the liver of the mouse, 2:2'-azonaphthalene may be converted into 3:4:5:6-dibenzoazobenzene, a polycyclic aromatic compound which is known to produce tumours at the site of application as well as in the liver. The present results are interesting in this connexion; but they are not inconsistent with such a view, for the absence of activity in the rat may be associated with a different metabolic pathway in this species.

Many substituted 4-dimethylaminoazobenzenes (for example, II) have already been tested for carcinogenic activity, and the results appear to be consistent with the view that activity is associated with an optimum density of electrons around the azo-linkage³. In agreement with the conception that there is an upper limit in electron density, 4:4'-di(dimethylamino)azobenzene (II, X = NMe₂) has now been shown to be entirely inactive (see table). Furthermore, 4'-methoxy-4-dimethylaminoazobenzene (II, X = OMe) was found to be moderately active, but less effective than 4-dimethylaminoazobenzene itself. All ten livers of this group showed varying degrees of diffuse fibrosis both to the naked eye and microscopically. Four of the ten showed localized white nodules varying from 4 to 10 mm. in diameter, which appeared to be neoplastic bile-duct epithelium. These areas often contained dilated cystic spaces having an angiomatous appearance. It seemed that tumours developed in the livers already showed bile-duct proliferation, the distinction between the two processes being rather subtle.

The amino-group seems to be essential for activity in this class of compound (that is, apart from azonaphthalene, which may act by a different mechanism), for 4-methoxyazobenzene and 4:4'-dimethoxy-

azobenzene (III, X = Y = OMe) were both found to be inactive.

We are indebted to Mr. H. R. Marston for the animals used in these experiments; we would also like to express our indebtedness to the University of Adelaide Anti-Cancer Committee for financial assistance.

Aromatic Aldehydes as Specific Chromatographic Colour Reagents for Amino-Acids

THOUGH some aromatic aldehydes have been used as amino-acid reagents^{1,2}; it was thought that a survey of available aromatic aldehydes would lead to the discovery of colour reactions useful in amino-acid chromatography.

The initial reaction between amino-acids and aromatic aldehydes is the formation of Schiff's bases. This, however, is only one of the possible reactions occurring. For example, hydroxyl substituted aromatic aldehydes have quinonoid potentialities and thus have carbonyl activity, in addition to that of the aldehyde group itself, which may result in more complex reactions. When the reagent contains the group $-\text{CO}-(\text{OH}=\text{CH})_n-\text{CO}-$, Strecker type reactions³ may occur. Also aerial oxidation may be a further complication.

In general, the method of investigation used was as follows. The range of common amino-acids were run on one-way chromatograms, 5 μ l. each of $M/100$ solutions being used. The sheets were dried and dipped in a 2 per cent solution of the aldehyde in acetone or *n*-butanol. The sheets were heated and observed in daylight and ultra-violet light. Benzaldehyde, cinnamic aldehyde, *p*-aminobenzaldehyde, and 2,4-dichlorobenzaldehyde give negative results; *o*-, *m*- and *p*-hydroxy-benzaldehyde give weak yellow colours with most amino-acids in daylight and ultra-violet light; ornithine and lysine give a strong yellow in the ultra-violet; 2,3- and 2,4-dihydroxybenzaldehydes give quite strong colours, but variable results occur with slight differences in heating. This is probably related to the complex reaction potentialities of the keto forms.

Vanillin gives red colours with ornithine and imino-acids when followed by 1 per cent alcoholic potash dipping⁴. The chromogenic reaction here is not a simple Schiff's condensation; for when the chromatogram is kept in an evacuated tube after alcoholic potash treatment and drying, the red colours with imino-acids do not develop. Thus aerial oxidation is probably involved. 2-Hydroxy-3-methoxy benzaldehyde gives similar results to vanillin but is rather less sensitive on the whole.

o-Phthalaldehyde has been previously used⁴ as a specific reagent for glycine, histidine and tryptophan.

We dip chromatograms in a freshly prepared 0.2 per cent solution of *o*-phthalaldehyde in acetone. When the chromatograms are run in acetone-water to which 0.4 per cent urea is added, glycine gives a purple spot instead of the usual green spot. The addition of 0.2 per cent urea to the *o*-phthalaldehyde solution produces a purple colour with glycine run in other neutral solvents. Butanol-acetic acid chromatograms are unaffected by urea. Glutamic acid shows as a red-brown spot under ultra-violet light after dipping in *o*-phthalaldehyde in the presence of urea and heating. This, however, is only observed after running in neutral non-aromatic solvents showing up well on acetone/urea chromatograms. We also find *o*-phthalaldehyde gives a specific colour reaction with taurine. The fluorescence given by histidine, tryptophan and tryptamine fades on excessive heating. The colour given by histidine is yellow only when relatively large amounts of the amino-acid are present; at lower levels it is pale blue. Indole gives no colour reaction. Amino-acids not mentioned give indefinite greyish spots in the presence of urea.

The colour reactions given by *o*-phthalaldehyde are strongly affected by the solvent in which it is dissolved. Apart from the sensitivity being greater in solvents of low boiling-point and high dielectric constant, which one would expect on general considerations, sensitivity is much greater in ketonic solvents than in alcoholic ones of similar dielectric constant. We find *o*-phthalaldehyde to be particularly satisfactory in acetone solution. We also confirm that isatin⁵ and ninhydrin⁶ are particularly effective amino-acid reagents in acetone solution. *o*-Phthalaldehyde, isatin and ninhydrin all have the structural unit required for the Strecker degradation, though this probably only represents a part of the sequence of reactions with amino-acids. Grove⁷ studied the reaction between glycine and *o*-phthalaldehyde and obtained a most complex series of products.

We find that 0.2 per cent terephthalaldehyde in acetone is a specific and sensitive reagent for histidine,

* The colours were observed in ultra-violet light of wave-length 3650 Å., with the exception of those given by glycine, which were observed in daylight.

tryptophan and tryptamine on paper-chromatograms. The difference between the histidine and tryptophan colours is much more clear-cut than with *o*-phthalaldehyde. While we were writing this communication, Jepson and Stevens⁸ reported that the fluorescence given with ninhydrin by tryptamine was much enhanced by addition of 10 per cent acetic acid to the ninhydrin solution. We also find that when terephthalaldehyde is dissolved in 10 per cent acetic acid in acetone more intense colours are observed with tryptophan and tryptamine. This indicates that the reaction mechanism is possibly similar to that postulated by Jepson and Stevens. Under these conditions, tryptophan gives an intense blue fluorescent spot which has a yellow centre at higher concentrations. Histidine, however, gives a less sensitive colour reaction. We thus recommend the acid reagent for tryptophan and tryptamine and the neutral reagent for histidine and for differentiation between histidine and tryptophan. *iso*-Phthalaldehyde gives similar results to terephthalaldehyde, but the sensitivities are lower. Comparison of results with *o*-phthalaldehyde and *iso*- and terephthalaldehydes indicates that the proximity of the aldehyde groups in the ortho isomer plays an important part in its reactivity towards amino-acids.

We thank Dr. J. B. Jepson, Mr. I. I. Smith and Mr. J. F. Grove for discussing this work with us, and for samples of various amino-acids and aldehydes

Separation and Identification of Alkali Metals on Paper Chromatograms

THE alkali metals do not readily lend themselves to detection on paper chromatograms by general or specific spot reagents, except in high concentration, as, for example, using hexanitro-diphenylamine as a spray reagent for the detection of potassium. A method has been developed which utilizes the production of an insoluble coloured precipitate when potassium, caesium, rubidium and the ammonium ion are treated with a solution of sodium cobaltinitrite. The paper chromatogram is run in the usual fashion and dried. It is then either heavily sprayed with or soaked in a solution of cobaltinitrite. The solution of Kramer and Tiedall¹ or a freshly prepared 10 per cent aqueous solution of solid sodium cobaltinitrite in 5 per cent acetic acid may be employed.

The paper is now washed in cold running water for two or three minutes in order to remove the excess of coloured reagent and reveal the 'spots' of yellow

cobaltinitrite of the respective ion. By this technique as little as 5 μ gm. of metal has been identified. The paper is allowed to dry in the air since, when heated, some fading of the spots occurs due to decomposition of the cobaltinitrite. The spot reaction appears to be specific for this group of ions; of thirty-two other metals tested, none gave a yellow spot by this treatment. If the paper is dried by heating and then sprayed with a 0.1 per cent alcoholic solution of α -nitroso- β -naphthol made alkaline with sodium hydroxide, the spots show brown against a pale green background. An increase in sensitivity is gained by this treatment, particularly in the case of ammonium.

This technique of applying a highly coloured reagent followed by washing out excess to reveal a coloured spot has been applied by me to the use of sodium alizarin sulphonate and of quinalizarin for the detection of a wide range of metals. The immediate formation of an insoluble precipitate permits the use of aqueous solutions of the reagents, and the production of compact spots free from any spreading.

Separation of the ions potassium, rubidium, caesium and ammonium was tested in a number of solvent systems. Chromatograms were irrigated by the ascending method¹ on Whatman No. 4 filter paper at 19° C. $\pm$ 1°. R_F values found are shown in the accompanying table.

It will be seen from the table that the only solvent among those tried which will separate all four ions is phenol. This is used equilibrated with 20 per cent (v/v) aqueous hydrochloric acid. The presence of the acid yields sharper spots than are obtained with water-saturated phenol. The accompanying photograph shows a test separation. This was carried out by the descending method using a 35-cm. solvent run. The solution containing about 50 μ gm. of each metal was applied as a narrow streak along the line marked 'original position'. Irrigation was with phenol-hydrochloric acid solvent; the spots were made visible by Kramer and Tis-

dall's reagent and photographed through a blue filter.

In practice, a solution may be applied directly for analysis, or a preliminary concentration and purification carried out by precipitation as cobaltinitrite followed by treatment with hydrochloric acid, evaporation to dryness and solution in water. The cobalt now present in solution runs to R_F 0.09 in phenol and has been shown not to modify the flow or separation of the alkali metals.

Mixed Crystals of Ice and Ammonium Fluoride

THE "inability of forming solid solutions with any compound" was attributed to water two years ago by Mironov and Bergman¹, who refuted previous reports by Giguere and Maass² and by Kubaschewski and Weber³ of the solubility of hydrogen peroxide in ice. Yet Kathleen Lonsdale⁴ directed attention to the fact that ice and ammonium fluoride are not only isomorphous but also give very similar diffuse star-shaped streaks on Laue X-ray patterns, which were attributed to thermal vibrations of hydrogen nuclei. This great similarity suggested that ice and ammonium fluoride might form mixed crystals.

We have therefore examined the solubility of ammonium fluoride in ice, and we obtained positive results by the following independent methods:

(1) Single crystals of ice frozen from solutions of 0.2 per cent ammonium fluoride gave invariably positive reactions for the ammonium ion when tested with Nessler's reagent, whereas crystals frozen under similar conditions from solutions of 0.1 per cent ammonia gave negative tests.

(2) Heating curves for finely powdered ice-ammonium fluoride mixtures showed different thawing temperatures for different concentrations of the latter. These are shown by the circles in Fig. 1.

(3) Dilatometric measurements on ice containing 0.7 per cent ammonium fluoride showed a sudden negative coefficient of thermal expansion at -4° C. which indicated incipient thawing. This is represented by a square in Fig. 1.

(4) Thermodynamic estimates of the solidus curve from data for the liquidus curve previously reported by V. C. Lamlov and E. M. Poliakova⁵ using the modified Clausius-Clapeyron relation:

$$\ln \left(\frac{\text{conc. water in liquid phase}}{\text{conc. water in solid phase}} \right) = \frac{\text{heat of fusion of ice}}{RT} + \text{constant}$$

agree well with the experimental values. The calculated values are represented by crosses in Fig. 1.

Fig. 1. Phase diagram for the system H_2O-NH_4F

(5) We have confirmed the observation of Workman and Reynolds⁶ that the resistivity of ice frozen from solutions of ammonium fluoride increases with the concentration of the latter. On the other hand, substances not forming solid solutions of ice, for example, ammonium chloride, caused an enormous decrease of resistivity with increasing concentration (from approximately 2×10^{11} ohm-cm. for pure ice to about 7×10^8 ohm-cm. for 0.05 *N* ammonium chloride at $-78.5^\circ C$).

(6) Finally, measurements of the dielectric constant of ice-ammonium fluoride at $-78.5^\circ C$. showed a large decrease in the dielectric relaxation time with the concentration of ammonium fluoride within the range of 10^{-4} to 0.1 per cent fluoride, followed by an increase for concentrations greater than 0.1 per cent. Such an effect would not be expected of eutectic mixtures.

These results prove the formation of mixed crystals between ice and ammonium fluoride in a limited range up to about 10 per cent fluoride.

More details about the above-mentioned experiments, as well as results of further work, will be given later. These investigations were carried out under contract No. DA-21-018-eng-500 of the U.S. Army Engineering Corps, Snow, Ice and Permafrost Establishment.

Conductivity Induced in Insulating Materials by X-Rays

MEASUREMENTS of the conductivity induced in insulating materials by X- and γ -rays have shown the existence of a long period decay¹, and more recent investigations²⁻⁴ have shown that the electron-trapping mechanisms which apply to photoconductivity also apply to these materials. This general picture may enable the energy-level distribution of the material to be elucidated. The present experiments have been concerned with polythene and 'Perspex', and have used a d.o. amplifier to measure the current induced by X-rays of 220 kV_p (half-value

layer = 2.5 mm. copper) both during and after irradiation.

The equilibrium induced current i in polythene is found to be related to the dose-rate R by the relationship:

$$i \propto R^{0.8 \pm 0.05} \quad (1)$$

over the range $R = 0.05-20$ r./min. and between 20° and $80^\circ C$. This is in agreement with the work of Mayburg and Lawrence⁵, who have reported the exponent in the above equation to be $\frac{4}{5}$. This value has been confirmed by Coleman⁶. It is not necessary to assume an ionic conductivity in order to explain either the value of this exponent or the variation of induced current with temperature.

Fig. 1. Distribution of electron traps in energy for polythene (Fig. 1) and 'Perspex' (Fig. 2): (A) conduction levels; (B) normally forbidden levels, with traps shown; (C) full levels

If the models of electron trapping suggested by Randall and Wilkins⁷ and by Rose⁸ can be applied to these materials, we are led to suggest that the distribution of electron traps below the conduction band in the case of polythene is exponential (Fig. 1). Further evidence in favour of this model for polythene is derived from the dependence on temperature and dose-rate of the decay of induced current: the time constant is long, varies slowly with temperature, and decreases with increasing dose-rate. This latter variation is reciprocal for low temperatures and dose-rates, but is proportional to $1/\sqrt{R}$ for higher values of i . The decaying conductivity is inversely proportional to time after about 10 min.; the deeper traps may therefore be distributed more uniformly in depth than the shallow ones.

Rose⁸ gives the variation of equilibrium photo-current with dose-rate and temperature for such a model as:

$$i \propto RNT/(T+T_1) \quad (2)$$

where N is number of energy-levels in the lower part of the conduction band "a few kT " wide, T is temperature of the material, and T_1 is an arbitrary temperature, which, however, may have some physical significance in terms of the molecular structure of the specimen.

For $T_1 = 1,200^\circ K$., the exponent in equation (1) is 0.8. The expression leads to an increase of induced current with temperature by a factor of about ten per $100^\circ C$. near room temperature, and agrees reasonably well with the variation already observed by us³ ($W = 0.42$ eV.), and with the value of $W = 0.3$ eV. obtained by Coleman⁶. Our subsequent measurements lead us to believe that the value is between these figures, probably $W = 0.35$ eV., and we feel that the agreement is becoming more satisfactory.

It is worth noting that the value of W in the relation:

$$\sigma = \sigma_0 \exp(-W/kT)$$

has been determined by Ramsay⁹ for previously irradiated polythene with no incident radiation during the measurement. He found a value $W = 1.45$ eV.,

in close agreement with the value $W = 1.5$ eV. reported by us².

Ramsey found that a new specimen of polythene, prior to any irradiation, gave $W = 0.5$ eV. It is likely that comparatively small doses of X-radiation (10^3 – 10^4 r.) will create new traps in the material at deep energy-levels. We have found a similar increase of activation energy in 'Perspex' from 0.5 eV. before irradiation to 1.2 eV. after less than 10^4 r. The new activation energy does not appear to decrease with time; indeed, measurements on the decay of the conductivity induced in the insulator of small cylindrical condensers by successive weekly doses of 10^4 r. suggest that such changes are not only permanent but also cumulative. Coleman and Bohm observed a similar effect in polystyrene under continuous long-term beta irradiation³.

Measurements similar to those described above for polythene have been carried out on 'Perspex', using a thin disk placed in a vacuum vessel with provision for controlling the temperature. Sheets of polythene have been used in this apparatus for confirming the results obtained with a flat coil of polythene cable, which are given above.

The induced current for 'Perspex' is of the same order as for polythene at 20° C., but the decay is more rapid by a factor of about ten. The dependence of induced current on dose-rate in 'Perspex' is given by:

$$i \propto R$$

over the range 0.5–30 r./min., and between 20° and 90° C. The induced current, moreover, is independent of temperature over these ranges. The time constant decreases with increasing dose-rate. These results suggest that in 'Perspex' the traps are distributed uniformly in depth^{4,5}, with a gap between the deep and the shallow traps (Fig. 2).

More detailed analysis of the growth and decay curves will, it is hoped, yield quantitative information on the distribution of energy-levels in these materials.

Possible Relation between Deoxyribonucleic Acid and Protein Structures

IN a communication in *Nature* of May 30, p. 964, J. D. Watson and F. H. C. Crick showed that the molecule of deoxyribonucleic acid, which can be considered as a chromosome fibre, consists of two parallel chains formed by only four different kinds of nucleotides. These are either (1) adenine, or (2) thymine, or (3) guanine, or (4) cytosine with sugar and phosphate molecules attached to them. Thus the hereditary properties of any given organism could be characterized by a long number written in a four-digit system. On the other hand, the enzymes (proteins), the composition of which must be completely determined by the deoxyribonucleic acid

Fig. 1

Fig. 2

molecule, are long peptide chains formed by about twenty different kinds of amino-acids, and can be considered as long 'words' based on a 20-letter alphabet. Thus the question arises about the way in which four-digit numbers can be translated into such 'words'.

It seems to me that such translation procedure can be easily established by considering the 'key-and-lock' relation between various amino-acids, and the rhomb-shaped 'holes' formed by various nucleotides in the deoxyribonucleic acid chain. Fig. 1 shows schematically the structure of the deoxyribonucleic acid molecule as derived by Watson and Crick. We see that each 'hole' is defined by only three of the four nucleotides forming it since, indeed, two nucleotides located across the axis of the cylinder are related by $1 \leftrightarrow 2$ and $3 \leftrightarrow 4$ binding conditions. It can easily be seen that there are twenty different types of such 'holes', as shown in Fig. 2. The first eight of them are simple, while each of the remaining twelve can exist either in right-handed or left-handed modification. It is inviting to associate these 'holes' with twenty different amino-acids essential for living organisms.

One can speculate that free amino-acids from the surrounding medium get caught into the 'holes' of deoxyribonucleic acid molecules, and thus unite into the corresponding peptide chains. If this is true, there must exist a partial correlation between the neighbouring amino-acids in protein molecules, since the neighbouring holes have two common nucleotides. There must also exist a correlation between adenine-to-guanine ratios in different organisms, and the relative amount of various amino-acids in the corresponding proteins. The detailed account of the proposed theory will appear in *Kong. Dan. Vid. Selsk.*

G. GAMOW

George Washington University,
Washington, D.C. Oct. 22.

FORTHCOMING EVENTS

(Meetings marked with an asterisk * are open to the public)

Monday, February 15

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY (at the University, Manchester), at 5.45 p.m.—Prof. A. C. B. Lovell: "Manchester's Great Radio Telescope" (Perovskii Lecture).

INSTITUTE OF METAL FINISHING, LONDON BRANCH (In Room 153, Jannought Building, Northampton Polytechnic, St. John's Street, London, W.C.1), at 6 p.m.—Discussion on "Technical Education—How It Can Help You".

INSTITUTION OF ELECTRICAL ENGINEERS, EDUCATION DISCUSSION GROUP (at Savoy Place, London, W.O.2), at 6 p.m.—Discussion on "The Teaching of the Subject of Insulating Materials".

SOCIETY OF CHEMICAL INDUSTRY, MICROBIOLOGY GROUP (In the Hall of the Institution of Structural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 6.15 p.m.—Dr. N. J. Berridge: "Inhibitory Substances of Bacterial and Other Origins in Milk and Milk Products".

Tuesday, February 16

BRITISH PSYCHOLOGICAL SOCIETY, INDUSTRIAL SECTION (In Room 105, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 1 p.m.—Mr. J. G. W. Davies: "Vocational Guidance in the Universities".

UNIVERSITY OF LONDON (In the Anatomy Theatre, University College, Gower Street, London, W.O.1), at 1.15 p.m.—Dr. J. L. Watling: "Is It Possible for Us to Know the Future?".

INSTITUTION OF ELECTRICAL ENGINEERS (at the Institution of Electrical Engineers, Savoy Place, London, W.O.2), at 2.15 p.m.—Mr. G. Henderson: "Mechanisation of Bracken Bracken".

SOCIETY OF CHEMICAL INDUSTRY, AGRICULTURE GROUP (In the Chemistry Lecture Theatre, Royal College of Science, Imperial Institute Road, London, S.W.7), at 2.30 p.m.—Dr. K. L. Robinson: "Antibiotics in Animal Feeding".

HUGENIUS SOCIETY (at Mason House, 28 Portland Place, London, W.1), at 6 p.m.—Prof. F. A. M. Crew, F.R.S.: "A Hugenic Appraisal of the Welfare State" (Galton Lecture).

BRITISH POSTGRADUATE MEDICAL FEDERATION (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.30 p.m.—Sir Neil Hamilton Fairley, F.R.S.: "Anti-malarial Drugs—Their Action in Different Stages of the Malaria Parasite in Man" (Tenth of fifteen lectures on "The Scientific Basis of Medicine").

INSTITUTION OF ELECTRICAL ENGINEERS (at Central Hall, Westminster, London, S.W.1), at 6 p.m.—Mr. O. W. Humphreys: "Electro-Heat and Prosperity" (Faraday Lecture).

Wednesday, February 17

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, W.O.2), at 2.30 p.m.—Mr. B. W. Marsh: "Modern Developments in Fungicide Research" (Farnham Lecture).

PHYSICAL SOCIETY, COLOUR GROUP (In the Physics Department, Imperial College, Imperial Institute Road, South Kensington, London, S.W.7), at 3.30 p.m.—Dr. L. O. Thomson: "A Study of the Appearance of Spectral Colours and their Relationship to Miller's Theory of Vision"; Prof. W. D. Wright: "Some Conservative Thoughts on the Trichromatic Theory".

ROYAL METEOROLOGICAL SOCIETY (at 49 Cromwell Road, London, N.W.7), at 5 p.m.—Scientific Papers.

ROYAL MICROSCOPICAL SOCIETY (at Tavistock House South, Tavistock Square, London, W.C.1), at 5.30 p.m.—Dr. B. G. White: "Microscopy of Antigens and Antibodies Within Tissues by the Use of Fluorescent Antibody".

BRITISH INSTITUTION OF RADIO ENGINEERS, LONDON SECTION (In the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Mr. W. D. Kemp and Mr. B. B. Greenhead: "Electronics in Film Making".

OVERSEAS SCIENCE STUDENTS ASSOCIATION (at the Society for Living Scientists Ltd., 5 Old Burlington Street, London, W.1), at 8.30 p.m.—Prof. H. Dingle: "The Origin and Nature of Science".

Thursday, February 18

ASSOCIATION FOR THE STUDY OF ANIMAL BEHAVIOUR (at Birkbeck College, Malet Street, London, W.C.1), at 10.45 a.m.—Symposium "Behaviour and the Nervous System".

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. H. P. Brodie and Mr. A. G. Gaydon: "The Harberg and of O₂ in an Oxygen Afterglow and in the Night Sky Spectrum"; F. J. M. Groosbeck and Mr. F. O. Tompkins: "The Decomposition of Solid Azides by Electron Bombardment".

INSTITUTION OF MINING AND METALLURGY (at the Geological Society, London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. W. B. Shalsh: "Production of Asbestos in South Africa".

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—of A. Zygmund: "On the Interpolation of Linear Operators".

PHYSICAL SOCIETY, ACOUSTICS GROUP (joint meeting with the Section of Metals, at 4 Grosvenor Gardens, London, S.W.1), at 5 p.m.—Scientific Papers.

PHYSICAL SOCIETY, LOW TEMPERATURE GROUP (In the Lecture Theatre of the Science Museum, South Kensington, London, S.W.7), at 8 p.m.—Report on the recent Congress of the International Union Physics at Houston, U.S.A.

SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDING MATERIALS GROUP (joint meeting with the CORROSION GROUP, at the Institution of Structural Engineers, 11 Upper Belgrave Street, London, S.W.1), at 6 p.m.—Mr. Hector Campbell: "The Use of Non-Ferrous Metals in Domestic Water Supply".

ROYAL AERONAUTICAL SOCIETY (joint lecture with the HELICOPTER ASSOCIATION, at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. F. J. O'Hara: "Helicopter Research".

CHEMICAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 7.30 p.m.—Scientific Papers.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. M. G. P. Stoker and Dr. B. P. Marmion: "The Clinical Picture and Epidemiology of Q Fever".

Friday, February 19

INSTITUTION OF MECHANICAL ENGINEERS (joint meeting with the INDUSTRIAL ADMINISTRATION AND ENGINEERING PRODUCTION GROUP, at Storey's Gate, St. James's Park, London, S.W.1), at 5.30 p.m.—Mr. L. H. Leedham: "The Impact of Development and Research on Production and Design".

UNIVERSITY OF LONDON (In the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. W. S. Feldberg: "On Some Physiological Aspects of Histamine".

SOCIETY OF CHEMICAL INDUSTRY, FINE CHEMICALS GROUP (In the Chemistry Lecture Theatre, King's College, Strand, London, W.O.2), at 7 p.m.—Scientific Papers.

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 9 p.m.—Dr. Karl T. Compton (U.S.A.): "High Voltage for Cancer Therapy and Food Sterilization".

Saturday, February 20

BIOCHEMICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 11 a.m.—Symposium on "The Chemical Pathology of Animal Pigments".

BRITISH PSYCHOLOGICAL SOCIETY (In the Psychology Department, University College, Gower Street, London, W.C.1), at 2.30 p.m.—Dr. Hannah Steinberg: "Experiments on Psychological Effects of Drugs".

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Mr. W. Watson: "Ancient Chinese Civilization".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

ANALYST (including micro-analyst) (with an honours degree or equivalent qualification) in the CHEMISTRY DEPARTMENT—The Secretary, The University, Aberdeen (February 17).

ASSISTANT EXPERIMENTAL OFFICER or EXPERIMENTAL OFFICER (preferably with a degree in botany or agricultural botany) at the Agricultural Research Council's Unit of Experimental Agronomy, Oxford, for field investigations connected with the development of herbicides and arboricides for vegetation control—The Secretary, Agricultural Research Council, Ounard Building, 15 Regent Street, London, S.W.1 (February 17).

HEAD OF THE DEPARTMENT OF CHEMISTRY—The Registrar, College of Technology, Suffolk Street, Birmingham (February 18).

ANALYST, Experimental Officer grade (with a recognised qualification in chemistry, and preferably with experience of analysis of soils and plants) in the NUTRITION OF FRUIT PLANTS SECTION at the Long Ashton Research Station (University of Bristol)—The Secretary, Research Station, Long Ashton, Bristol (February 20).

ASSISTANT EXPERIMENTAL OFFICER (graduate, preferably with some previous experience in bacteriological work) in the BACTERIOLOGY DEPARTMENT, to take part in research on the intestinal flora of the pig—The Secretary, National Institute for Research in Dairying, Shinfield, near Reading, quoting 54/1 (February 20).

BIOCHEMIST (honours science graduate) for research duties in the Geriatric Department of the Sunderland Hospital Group—The Senior Administrative Medical Officer, Newcastle Regional Hospital Board, "Blythwood South", Osborne Road, Newcastle-upon-Tyne 2 (February 20).

ENGINEERS AND PHYSICISTS (with first- or second-class honours degree in physics or engineering) in the ELECTRONICS DIVISION, for work ranging from fundamental research of electricity and the physics of nuclear radiation detectors to designing and developing electronic devices for the Atomic Energy Project—The Establishment Officer, Atomic Energy Research Establishment, Harwell (February 20).

HEAD OF SCIENCE DEPARTMENT—The Education Officer, Bournemouth Municipal College of Technology and Commerce, Bournemouth (February 20).

ANALYTICAL CHEMIST, Assistant Lecturer grade, in the DEPARTMENT OF AGRICULTURAL CHEMISTRY—The Registrar, Wye College, near Ashford, Kent (February 23).

CHEMIST (with some knowledge of bacteriology, biochemistry, or the chemistry of soils or sewage) with the British Electricity Authority, to study the effects on rivers of power station operations—The Director of Establishments, British Electricity Authority, Winsley Street, London, W.1, quoting T/449 (February 23).

BIOCHEMIST, Scientific Officer grade, in the Older and Fruit Juices Section, at the Long Ashton Research Station, Bristol (University of Bristol)—The Registrar and Secretary, The University, Bristol (February 27).

HEAD OF THE PHARMACY DEPARTMENT—The Principal, Brighton Technical College, Brighton 7 (February 27).

GRADUATE (with first- or second-class honours in geology and training in mineralogy and crystallography) in the DEPARTMENT OF PEDOLOGY, X-RAY SECTION—The Secretary, Macanlay Institute for Soil Research, Craigiebuckler, Aberdeen (February 28).

ASSISTANT (with at least H.S.C. with a science subject or General Certificate of Education to advanced level in a science subject, or equivalent) at the Nature Conservancy's Biological Research Station, Fursbrook, near Wareham, Dorset, to take entire responsibility for care and maintenance of the research laboratories.—The Establishment Officer (L), The Nature Conservancy, 91 Victoria Street, London, S.W.1 (March 1).

LECTURER (with special qualifications in paleontology) in the DEPARTMENT OF GEOLOGY.—The Registrar, Queen Mary College, Mile End Road, London, N.1 (March 1).

SCIENTIFIC OFFICER (preferably with a degree in chemistry, F.R.I.C. or other suitable qualification, and with practical experience in water and/or sewage treatment, and in the physical, chemical and bacteriological examination of water supplies), and a **JUNIOR ASSISTANT** (experienced in chemical analysis of sewage and trade effluents) at the Sewage Treatment Works, Crawley Development Corporation.—The Chief Engineer (Vacancy), Broadfield, Crawley, Sussex (March 1).

SENIOR LECTURER IN EDUCATION at the University of Natal, Durban, South Africa.—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Durban, March 1).

RESEARCH ASSISTANT IN PSYCHOLOGY at the University of Durham.—The Secretary, 28 North Bailey, Durham (March 4).

RESEARCH ASSISTANTS (2) (with special qualifications in physical chemistry, and preferably with previous experience in some branch of polymer science) in the DEPARTMENT OF CHEMISTRY.—The Registrar, The University, Manchester 13 (March 12).

ASSISTANT LECTURER IN MEDICAL BIOCHEMISTRY—The Registrar, The University, Leeds 2 (March 15).

DEVELOPER (with high qualifications in one of the sciences bearing on animal health, and considerable research and administrative experience) of MORFUDIN INSTITUTES.—The Secretary, Animal Diseases Research Association, Morfudin Institute, Gilmerton, Edinburgh (March 31).

PROFESSOR OF CHEMISTRY at the University of Otago, Dunedin, New Zealand.—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (Dunedin, March 31).

PROFESSOR OF PHYSICAL CHEMISTRY, a PROFESSOR OF CHEMICAL ENGINEERING, and a SENIOR LECTURER, in the DEPARTMENT OF CHEMISTRY, University of Natal, South Africa—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, March 31).

SENIOR LECTURER in the DEPARTMENT OF CIVIL ENGINEERING at the University of the Witwatersrand, Johannesburg, South Africa.—The Secretary, Association of Universities of the British Commonwealth, 5 Gordon Square, London, W.C.1 (South Africa, March 31).

LECTURER in BIOCHEMISTRY—The Secretary, Queen's University, Belfast (April 30).

ASSISTANT, Grade "B" (graduate or A.R.I.C.) in CHEMISTRY, in the Department of Chemistry, Colour Chemistry and Dyeing.—The Principal, Technological College, Queen Street South, Huddersfield.

ASSISTANT METEOROLOGISTS (with H.S.C., or equivalent in mathematics or physics, and preferably with forecasting experience) with the Nigerian Government.—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M8B/33458/TA.

CHEMIST (with an honours degree in chemistry from a British university) in the GEOLOGICAL SURVEY DEPARTMENT, Federation of Malaya, for the analysis of minerals, rocks and metallurgical alloys.—The Director of Recruitment, Colonial Office, Great Smith Street, London, S.W.1, quoting ODB106/60/02.

ENGINEERS AND PHYSICISTS, Senior Scientific Officer and Scientific Officer grades (with an appropriate first- or second-class honours degree or equivalent high professional attainments) in Royal Naval Scientific Service Experimental Establishments in London, Portsmouth, Weymouth and Gloucestershire areas, and in Scotland.—The Ministry of Labour and National Service, Technical and Scientific Register (K), 26 King Street, London, S.W.1, quoting A.244/52/A/R.2.

EXPERIMENTAL LECTURER (with high academic qualifications in pure science, preferably in physics or chemistry) in SCIENCE, in the Department of Extra-Mural Studies, King's College, Newcastle-upon-Tyne.—The Director of Extra-Mural Studies, Joseph Cowen House, 145 Barras Bridge, Newcastle-upon-Tyne 1.

MASTER (preferably with first- or second-class honours, Oxford or Cambridge) to teach MATHEMATICS to University Scholarship standard.—The Headmaster, Haberdashers School, Westbere Road, London, N.W.2.

PHYSICISTS (with a good honours degree) to assist in research into the fundamental principles underlying the processing of textile fibres into yarns.—The Secretary, The British Jute Trade Research Association, Kinnoull Road, Kingsway, West Dundee.

PRINCIPAL SCIENTIFIC OFFICER or SENIOR SCIENTIFIC OFFICER (with first- or second-class honours degree, or equivalent in physics, and at least three years experience in the construction and operation of mass-spectrometers, and extensive knowledge of their use in both qualitative and quantitative observations) at the Atomic Weapons Research Establishment, Aldermaston, Berkshire, to undertake research and development work in mass spectrometry.—The Administrative Officer, Recruitment, Atomic Weapons Research Establishment, Aldermaston, Berkshire, quoting 01/WGB.

SENIOR PHYSICIST IS REQUIRED TO change of an electrical research section of Laboratories which deals with long-term development work associated with automobile electrical equipment and with the design of electrical instrumentation, etc., to meet the needs of engineering sections. Applicants should have an honours degree with practical development or research experience and a bias towards electronics. The salary will be commensurate with the responsibility which the position carries. There are excellent prospects for advancement. Reply, stating qualifications, experience, age, to Personnel Manager, J. Lucas, Ltd., at King Street, Birmingham, quoting Reference: PM/D/91

UNILEVER, LIMITED, HAVE A VACANCY in their Patent Department for a qualified Chemist, Physicist, or Engineer, preferably with an honours degree. Previous experience in patent work is desirable, but not essential. The position will provide extensive experience in all aspects of British and foreign practice, and the opportunity to qualify as a patent agent. Applications, giving age and full particulars of qualifications and experience, to Personnel Division (B 57), Unilever House, Blackfriars, London, W.C.

GRADUATE CHEMIST, AGE 22 TO 30, REQUIRED for research and development work on synthetic resin emulsions by a company expanding its interests in this field. Salary according to qualifications and experience. Personnel Manager, Dunlop Rubber Co., Ltd., Fort Dunlop, Loughborough, 24.

PHYSICIST REQUIRED TO CONTROL THE physics section of a research and development laboratory. Applicant would be required to work with chemists, metallurgists, and ceramists in developing a variety of semi-conductors, ferroelectric and ferromagnetic materials for the electronic, radio and radar industries. Measurements of the dielectric properties of these materials would be an important part of the work. Applicants should have either an honours degree in physics with a minimum of three years' experience, or a Ph.D. degree will depend on experience and qualifications. Box 837, T. G. Scott & Son, Ltd., 143-147 Fleet Street, London, W.1.

YOUNG LABORATORY ASSISTANT REQUIRED, preferably possessing general certificate of education (advanced level), with one or two years' experience in microbiology. Apply Research Department, Barclay Perkins and Co., Ltd., Brewers, Park Street, London, S.E.1.

FOR SALE AND WANTED

WANTED, THE FOLLOWING HEFTE Pascher's *Schweser-Flora*: 1, 2A, 2B, 3, 5, 6, 7, 8, 13, and supplements to 4, 11, and 12—Headmaster, Gosport High School, Gosport, Hants

GRANTS & SCHOLARSHIPS

BRADFORD EDUCATION COMMITTEE TECHNICAL COLLEGE, BRADFORD DEPARTMENT OF CHEMISTRY AND DYEING WOOL TEXTILE RESEARCH COUNCIL SCHOLARSHIPS

Applications are invited for the following two Research Scholarships, each of the annual value of £300. 1. A Scholarship for research on spectroscopic problems connected with colour constitution. 2. A Scholarship for the investigation into the effect of the modification of fibre on dyeing properties, including electron-microscopy studies. Applicants should have a university degree (or equivalent), with chemistry as a principal subject. Further details may be obtained from the Principal, Technical College, Bradford, 7

UNIVERSITY OF LIVERPOOL

Applications are invited for four Fellowships, value £300 per annum each, and five Postgraduate Studentships, value £200 per annum each, in engineering (including mechanical, civil, and electrical engineering, electronics, and metallurgy). Applicants, which should include particulars as to age, academic qualifications, experience, and the proposed subject of research, together with the names of three referees, should be received not later than April 30, 1954, by the undersigned, from whom further conditions may be obtained. **STANLEY DUMBELL,** Registrar

ROYAL HOLLOWAY COLLEGE

(UNIVERSITY OF LONDON)
POSTGRADUATE STUDENTSHIPS, 1954-55
Studentships of £40 eligible for supplementation by the Ministry of Education are offered for the Session 1954-55, with the possibility of renewal for a second year, to men and women who are graduates (in arts or science) of any university. Studentships of £60 eligible for supplementation by the Ministry of Education are offered for the Session 1954-55, with the possibility of renewal for a second year, to women who are graduates (in arts or science) of any university. Particulars may be obtained from the Registrar.

Applications should be forwarded to the Principal, Royal Holloway College, Englefield Green, Surrey, not later than June 8, 1954. The awards will be made in the latter part of July, 1954.

BURSARY (£400 PER ANNUM) FOR honours graduate in mechanical engineering, to work for higher degree on development of expansion engine (low temperature plant design). Applications to Registrar, Imperial College, Prince Consort Road, S.W.7.

MISCELLANEOUS

BUCKINGHAMSHIRE EDUCATION COMMITTEE

Tenders are invited for the supply of the following classes of Equipment to the new Wolverton College of Further Education: (1) Machine Tools (2) Heat Engines, (3) Heat Engines (Hydraulic), (4) Sheet Metal Working, (5) Advanced Mechanics and Physics, (6) Heat Treatment and Forging.

Firms interested should make application to me immediately for tender forms and should indicate the class(es) of equipment for which they wish to tender. The closing date for the receipt of tenders will be March 6, 1954.

A short history of graticules—No. 1.

In the beginning...

Our story opens in 1639 with William Gascoigne, for he appears to be the inventor of the eyepiece micrometer, although crosswires were known even at that time. In that year he devised a method of measuring the size of planets by having two pointers moving in opposite directions which could be adjusted to the size of the planet being viewed. But it was not until 1667 that this invention was made public by Townley.

Meanwhile, the Italian, Divini, had drawn a pattern of straight lines on a convex glass in ink or with a diamond as an aid to measuring the size of planets. His efforts were not successful, but in 1662 the Marquis de Malvasia, inspired by Divini's suggestions, described a method of making a wire trellis, and this was used to observe the eclipse of 1666.

VACUUM COATING

in the service of **SCIENCE AND INDUSTRY**

Shadow-casting auxiliary for optical and electron microscopy work.

A rotary work holder for coating large quantities of intricate areas.

THESE ACCESSORIES GIVE SOME IDEA OF THE VERSATILITY OF VACUUM COATING AND THE COMPLETENESS OF EDWARDS RANGE OF COATING EQUIPMENT

Optical work holder for anti-reflection films or 'Blossoming'.

Automatic vacuum-sealed work holder and evaporation (for metallizing face and neck as required) arrangement for C.R.T.

Static work holder for aluminizing head-lamp reflectors. Holder can be adapted for any size reflector.

Work holder for quantity coating of quartz crystals with an r.f. frequency control.

Work chamber designed for metallizing rolled areas of paper, plastics, etc.

for better vacuum service... **W. EDWARDS & CO. (LONDON) LTD.**
MANOR ROYAL CRAWLEY, SUSSEX

DISTILLED QUALITY WATER

Wherever you need distilled water — in laboratory, factory or shop — you can use 'Deminrolit Water' with equal results. The Portable 'Deminrolit' plant operates by ion exchange and delivers water substantially free from dissolved solids. Running costs are measured in pence instead of in pounds, and you can thus use distilled quality water for many purposes where the cost of distillation would prove prohibitive. Please write for Technical Publication No. 62 which gives full details.

PERMUTIT 'DEMINROLIT'

THE PERMUTIT COMPANY LIMITED

(Dept. V.H. 173), Permutit House, Gunnersbury Avenue, London, W.4.

HIRE SERVICE

Why not try demineralised water in your industry? You can do so easily and cheaply by hiring from us, at a nominal rental for a trial period, the latest Mark II Model Portable 'Deminrolit' Plant. Details of this service will gladly be supplied on request.

Telephone: CH15wick 6431

*Save time,
save labour, by* **PHOTO-COPYING** *on the spot*

A PERFECTLY ACCURATE COPY of any document in under 3 minutes...

'Duostat' Photo-Copying Equipment gives you that—and has a lot of other advantages, too. For instance:

The job is done right in your office (no need to let confidential papers out of sight). No camera or darkroom. No dishes or running water. It's a quick, clean, simple process, carried out on an ordinary desk or

table by ordinary room lighting. Your office junior can do it.

Anything from a business letter to a complicated graph can be copied this way. The copies are photographic facsimiles. They need no checking—copying errors can't happen.

'Duostat' Equipment takes a load off typists' shoulders. It frees staff for more productive work. It's an investment in office efficiency. Post coupon for details.

SCIENTIFIC AND TECHNICAL MAN-POWER IN BRITAIN

IN recent years it has been increasingly recognized that the research associations in Great Britain have an important part to play in technical and technological education. In part this arises out of the greater emphasis which has been placed on their function of securing the greater utilization by industry of existing knowledge. From one point of view this is an educational function; but the research associations can also to some extent help in providing the industries they serve with trained scientific and technological staff. The university-trained scientist may frequently thus acquire the technical knowledge or technological skill which he might find it less easy to acquire in the smaller firm.

There are at present strict limits to what is possible in this way; but the movement of staff from the research associations into industry, and especially if there is some reverse flow, could materially contribute to the fuller staffing of industry with technically trained men able to appreciate the significance of new knowledge and apply it to productive purposes: it could also help to bring the research associations into more intimate touch with industry. The possibilities here may well deserve closer study than they have yet received, and it is therefore appropriate that the rôle of the research associations in technical and technological education should have been the subject of a private conference in London on November 27, attended by the Advisory Council for Scientific and Industrial Research, the chairman and directors of the research associations and some representatives of the universities and technical colleges. Discussion at this conference ranged over a wide field, but was concerned with the relations between the universities and technical colleges and the research associations, rather than between the latter and industry.

Special stress was laid on the value of experience with a research association in providing the graduate with the opportunity for extending his background and gaining appreciation of the technological problems of industry. If, as was asserted by some speakers, university regulations for the admission of students for postgraduate work are too restrictive, relaxation of such regulations so as to permit postgraduate studies under appropriate conditions in research association laboratories might, indeed, prove to be in the national interest, and the conference thought this should be encouraged. It was also recognized that there are possibilities in the exchange of staff and experience between the technical colleges and the research associations which might be further explored, and the conference will doubtless stimulate some further examination of the possibilities of closer collaboration generally by the bodies responsible. Meanwhile, the Department of Scientific and Industrial Research and the Ministry of Education are to arrange for fuller information about the research associations to be available to the technical colleges and vice versa.

The conference is to be welcomed as putting the research associations officially in the general scheme for higher technological education in Great Britain. No policy can now be regarded as complete which does not pay regard to the nature and the magnitude of the contribution which they could make to the training of technologists, of technicians and, indeed, of men for management. From this point of view, because the contribution of the research associations, to be fully efficient, must be interlocked with that of the universities and the technical colleges, the announcement made by Sir Ian Hailbron about the new financial arrangements for the Department of Scientific and Industrial Research is welcome and important. The greater flexibility which the Department will enjoy in planning its educational work, as well as its research, now that unspent monies are no longer to be surrendered at the end of the year, should enable the research associations to plan such developments with the continuity which the quinquennial grants policy has long permitted to the universities.

This is probably the most important feature of the change of Government policy towards the Department which Sir Ian announced. It means that neither a particular research association nor the Department in general need hesitate in future in embarking on some promising research or development which requires more than a year of continuous work before valuable results can be expected, for fear that Government decree would impose financial stringency. It should facilitate both the recruitment of scientific and technical staff of higher calibre and also the interchange of staff with industry and the universities, which was recognized by the conference to be so valuable.

Such consequences, with the interlocking of the work of the research associations and of the Department generally with the whole effort of Britain in scientific and industrial research and in higher technological education; may well be far more important than the actual expansion of the Department's work on which Sir Ian laid considerable stress. With rising costs, the further £6 million expected to be available for new building over the next five years is unlikely to go much further, if so far, as the £1 million a year which it was estimated in 1945 would be required for capital expenditure. Much the same may well apply to the additional £800,000 which the research associations are to receive from the Treasury over the next five years, bringing the Department's contribution from about £1,333,000, out of a total of some £4 million in 1952-53, to about £1,680,000 in 1958-59, when the Department's total expenditure, including about £4,500,000 on its own research establishment, will exceed £6 million a year.

However, although these increases may be less substantial than they seemed at first hearing, and the actual scale of research is unlikely to be increased greatly, the risk of waste of effort and frustration has been greatly diminished, and anxieties expressed in the last two reports from the Advisory Council for Scientific and Industrial Research should be largely removed. Effective planning of research on reason-

ably firm budgeting expectations for several years ahead becomes possible, and the execution of the Department's post-war plans for expansion should bring the scientific needs and resources of Britain into a more satisfactory relation. The basis at least is provided for consolidation as well as for expansion.

It is not only in the field of technical education, however, that the work of the research associations in particular, or of the Department in general, requires consideration in relation to the country's resources and effort in other fields. The new proposals, for example, mean that the Department will recruit yearly a further one hundred and fifty non-industrial and about fifty industrial staff, and will thus be competing further with industry and the universities for the present inadequate supply of science graduates. This is a further reason for early action for dealing with the shortage of science teachers in schools upon which any increase in the supply of science graduates depends. Something much more than the minor suggestions of the report of the National Advisory Council on the Training and Supply of Teachers will be required if the Department is not to find its plans for expansion during the next five years hindered by difficulty in recruiting staff. The Department is as deeply concerned as industry itself with the shortage of science teachers.

It is equally important that an attempt should be made to assess the magnitude and distribution of the nation's research effort in relation to its resources—both in materials or in man-power. One reason for welcoming the Government's proposal to transfer the control of the development of atomic energy from the Ministry of Supply to the Atomic Energy Corporation under the Lord President of the Council is that, provided the Lord President has the requisite staff for his extended functions, a comprehensive review of that effort and those resources should be possible at Cabinet, rather than departmental, level. That much was appreciated by at least some of the speakers on both sides of the House in the debate in the Commons on December 10; but it was equally clear that other members of Parliament have little understanding of what is involved. The arguments against the Order in Council which gives effect to the transfer of functions were ill-judged and, as Viscount Hinchinbrook and Sir David Eccles had little difficulty in showing, largely irrelevant. The really important point was missed. That the present Lord President happens to be in the House of Lords may be fortuitous, as Sir David Eccles said: the magnitude of his scientific and his financial responsibilities are now such, however, that concern can reasonably be felt that there should be no direct spokesman in the House of Commons.

It is not the transfer of functions that is open to question on scientific, technical or administrative grounds, but the tactical omission to provide an appropriate direct spokesman in the House of Commons. The point is one to which the Government should give further attention, and it might well be examined by the Parliamentary and Scientific Committee. So much depends on public confidence,

especially in fields where security reasons hinder anything like full public discussion, that a Government gesture here could do much good. As it stands, that confidence must be earned by the vigour and efficiency with which the Government conducts its policy over the whole field of science and technology. The Lord President of the Council is now in a position to concert an adequate policy. It has yet to be seen whether he has the will and determination to secure the effective implementation of his policy.

Such a policy has two main aspects. One is that of materials and finance. It is this economic aspect that has received most discussion; although, because of the extent to which the expenditure of finance and materials on defence purposes overshadows such expenditure for civil purposes, public discussion here is most hindered by security considerations. A major advantage of the new arrangements for the development of atomic energy is that they bring into the area of public discussion a large segment of the expenditure previously included under the vote of the Ministry of Supply and reaching some £150 million for "Research and Development" in 1952-53. Even if it is still not possible for the headings to be broken down in detail, it should be possible for the nation to gain some rough idea of the relative effort expended on nuclear research in comparison with the total research effort, and accordingly for some independent attempt to assess whether or not that effort is out of balance.

The value of that gain cannot yet be judged fully. Meanwhile, it should be possible for the Lord President to satisfy Parliament that the weaknesses in the organization of research and development effort indicated by the Select Committee on Estimates in its third report for the session 1946-47 and the sources of overlapping and waste of effort there and in relation to defence expenditure to which the Select Committee directed attention in its reports for the session 1948-49, are being carefully watched, and that every reasonable step has been taken to secure co-operation. At a time when difficult decisions in regard to new weapons have to be taken, it is important, just because those decisions and the reasons for them cannot be made public, that Parliament should be given the fullest possible grounds for confidence that there is no administrative slackness or departmentalism hindering co-operation and the effective use of all relevant scientific and technical advance. No such reports have come from the Estimates Committee since the Advisory Council on Scientific Policy became fully operative, and fresh inquiry might be useful.

The second main aspect of policy arises at exactly that point—the use of scientific and technical manpower. This is probably at the present time the most urgent and critical aspect of Britain's whole security: defence and economic security alike turn on her resources of scientific and technical manpower and the use which is made of them. The Government's decision to allow the expansion of the Department of Scientific and Industrial Research to proceed contemplates an increase in the staff of that Department over the coming five years of about

1,000, bringing it to a total of 5,100 in 1959, when the Department should be able to cover some 95 per cent of the activities projected in the 1947-48 plans. It is not yet disclosed what further demands on scientific manpower the plans for atomic energy development will make, but the recommendation of the Advisory Council on Scientific Policy in its last report that more scientists and technologists should be employed in industry has been emphatically endorsed in various quarters.

The implications of the present situation have been brought out in the recent report of the National Advisory Council on the Training and Supply of Teachers. Dealing particularly with graduate teachers of mathematics and science, the report points out that industry is at present taking at least one-third of the annual output of men graduates in mathematics and science at first-degree level, and a good proportion of those who have just completed a period of postgraduate research. Some forty per cent take up research or postgraduate courses or university teaching, and about twenty per cent take up teaching in schools or technical colleges. Of those who obtain honours degrees, some thirty per cent enter industry or commerce, forty-five per cent take up research, postgraduate work or university teaching, and only fifteen per cent go to teach in schools or technical colleges.

The industrial demand for physicists and chemists is still strong, and, although a slackening in the demands for defence might lead to a slight easing of the position there, the unsatisfied demand from industry generally is likely to take up any surplus. Moreover, Prof. M. B. Donald has recently asserted that five times as many chemical engineers are required by British industry as the universities are producing, and Lord Simon told the Court of Governors of the University of Manchester recently that twice the number of engineering graduates now produced could be immediately absorbed by industry. There were two hundred places for engineering students in the universities and colleges of Great Britain which were unfilled last year for lack of suitable applicants. The principal of the Manchester College of Technology, Dr. B. V. Bowden, has also stated that the College could place in good positions at least twice as many graduates as it turns out in a year, and that in some of its departments there is room for thirty to fifty per cent more students.

There is thus no probability of a decreased, but rather of an increased, demand for scientists and technologists for industrial purposes in Great Britain, and especially for work which bears on the improvement of productivity or the export trade. It is in this situation that the inadequacy of the supply of mathematics and science graduate teachers, both in quantity and in quality, to meet the current requirements of schools and technical colleges has to be considered. The average annual requirement over 1955-60 is estimated at more than fifty per cent greater than the present figure, although the National Advisory Council was unable to measure the deficiency exactly from the statistics available. What is unquestionably true is that the standard of

those taking up teaching, as indicated by the degrees they hold, has fallen conspicuously, and that the fall in numbers and quality of science teachers is already affecting the number of students taking courses in science and engineering.

If, therefore, research and development, either in industry, in the public corporations or in Government departments, are not to be impeded by shortage of scientific and technical man-power, the supply of science teachers is a matter demanding urgent and careful action. Something can, of course, be done, both by industry and by the universities, to ease the present situation by looking closely at the use they make of graduates, so as to ensure that graduates are not employed on work that could equally well be done by those less highly qualified. Probably the schools have already done as much as possible to avoid waste of science graduates in classes which do not call primarily for a science graduate, though the report directs attention to the possibilities which a wider use of laboratory assistants in the schools offers.

The recent conference of industrial and educational interests arranged by the Federation of British Industries to consider the problem as it affects industry led to valuable discussion, but the overriding need is still for a policy for scientific and technical man-power, and for this the Government must bear the main responsibility. So far as the shortage of science teachers is concerned, the Ministry of Education cannot escape censure for failure to take energetic action to deal with a situation which has long been apparent qualitatively. To the same Ministry's dilatoriness is largely due the failure to formulate even after months an effective policy for the expansion of the technical colleges. The reply of the Chancellor of the Exchequer, Mr. R. A. Butler, when pressed on this point in the House of Commons on December 8, indicated that while, at the technological level, the Government has in mind the development of at least the Manchester College of Technology as well as the Royal Technical College, Glasgow, expansion at the level of the technical colleges is also contemplated; but he gave no indication that there is to be any balanced and concerted policy.

We require, in fact, not merely an estimate of the national need for scientific and technical man-power which fills the gaps in the survey made for the Advisory Council on Scientific Policy: we need also an estimate of our requirements in regard to technical man-power. Only then will a policy for higher technological education be possible, for it must be in balance with our policy for technical education. The danger of the present piecemeal approach is that the upgrading of technical colleges for the training of technologists may be determined by sectional or local rather than national interests, and may deflect them from the vital task of training the even greater number of technicians that will be required.

An objective view of this whole situation is the first requirement. Without it there is danger that by over-rigid insistence on standards we may expend higher technological education too late and too much,

while failing to expand technical education at the lower level so that industry is provided with the further two or three thousand additional students, not necessarily university graduates, which would make all the difference to technological progress. Short-term measures are required to meet the immediate situation; but they must be in keeping with the long-term measures which are required to provide the permanent steady stream of scientists, technologists and technicians which industry and government and university establishments as well as the schools will require in future.

THE STUDY OF VIRUSES

Advances in Virus Research

Edited by Kenneth M. Smith and Max A. Lauffer.
Vol. 1. Pp. xi+362. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1953.)
8 dollars.

IN the preface to this book, the first of a series which is expected to appear annually, the editors comment on the wide range of periodicals in which articles on viruses now appear. Their commendable aim is to avoid this scatter, at least of review articles; but whether they will succeed only time will tell. Success will probably demand more than what politicians call 'unilateral action', and editors of other series may not automatically forgo their interests in these topical pathogens. More likely, "Advances in Virus Research" will add another to the list of publications virus workers must consult, differing from the others, however, in dealing only with the study of viruses. That the subject now has its own volume is gratifying evidence that it has 'come of age'; but less pleasing is the almost inevitable consequence that workers in it will increasingly be called by the bastard name 'virologist'.

The contents of this volume are said to indicate the scope of the series, in which "the focus of interest is to be the virus". They are: the properties of bacteriophages (H. T. Epstein); interactions between viruses and virus strains (C. W. Bennett); transmission of plant viruses by Cicadellids (L. M. Black); insect viruses (G. H. Bergold); multiplication of influenza virus in the endodermal cells of the allantois of the chick embryo (W. Henle); poliomyelitis (J. L. Melnick); purification and properties of animal viruses (D. G. Sharp); and virus nucleic acids (R. Markham).

The titles show that the series deals with viruses which infect all kinds of organisms; but they do not all accurately reflect the contents or show that the amount of detail given by different authors varies enormously. Epstein's article has a wide title covering one of the most active branches of virus research, but occupies only thirty-five pages, which include twelve sizeable text-figures; it is typical of his summary treatment that lysogenic bacteria get one short paragraph. In striking contrast, Henle's article, with the narrowest of titles, runs to eighty-two pages of unremitting text; the last paragraph starts by saying that "the foregoing sections will have amply demonstrated that the current knowledge concerning the multiplication of influenza virus is still rather limited". Fortunately the contents are more valuable than this quotation suggests, for they

go far beyond the title and cover most kinds of work on influenza virus. Melnick's article, too, has a misleading title; it is not at all concerned with poliomyelitis as a disease, but is an admirable account of current knowledge on the virus. Bennett's is probably the best account yet given of his subject; but the subject is narrower than the title suggests, for he considers only plant viruses.

Two articles deal with insects, one as vectors of plant viruses and the other as sufferers from infection. Black's can be paid the compliment of saying that many who live where leafhopper-transmitted viruses are not yet troublesome would have welcomed more detail. Bergold shows his belief that viruses are organisms by being the only author to give them Latin binomial names, which, incidentally, are already invalid. His apparent lack of interest in the fascinating problems raised by the survival of 'latent' viruses through many generations of insects seems unaccountable.

Markham's essay will be valued by the many pathologists who know little about either the structure or functions of nucleic acids; but it is to be hoped they will not take resistance to nucleases as 'direct evidence' that nucleic acid is held internally in viruses. It may well be, but if we reason the same way from their resistance to proteases, the protein, too, must be held internally. In attempting to cover too much, Sharp has produced a rather scrappy result, which will be useful mainly as a guide to the literature.

At the start of a series, it was perhaps deliberate policy to summarize broad subjects; but this should not continue. This volume amply shows that more satisfactory articles come from the critical examination of limited topics. In future volumes, too, references should be cited uniformly; some authors now refer by numbers whereas others use the better method of names with dates, and some list only journal references whereas others give the titles of papers.

The volume is excellently produced, with detailed author and subject indexes. In the United States the price may seem reasonable; but for the sterling area it is regrettably high.

Introduction to Statistical Calculations

By J. Mounsey. Pp. 351. (London: English Universities Press, Ltd., 1952.) 15s. net.

Statistical Tables and Problems

By Prof. Albert E. Waugh. Third Edition. Pp. xiv+242. (London: McGraw-Hill Publishing Co., Ltd., 1952.) 25s. 6d.

GOOD exercises in statistics are hard to find. The essential statistical point is apt to get lost in arithmetical calculations or in pure mathematical analysis. Artificial examples lose that contact with reality which all statistical teachers try to maintain; and examples from the real world become contaminated with practical considerations which are off the essential point. Some statistical text-books do not attempt the setting of exercises at all; and,

among those which do so, there are often many trivial examples and a shortage of good solid ones on which the student may test his knowledge, his grasp of fundamentals and his technical expertise.

The volumes under notice are attempts to fill this gap. The exercises from University College, London, are based on an unrivalled experience of class-work accompanying first-year lectures to undergraduate students taking the B.Sc. (Special) degree in statistics of the University of London. They are all numerical and, broadly speaking, cover univariate theory, regression and correlation, chi-squared and significance tests, sampling distributions and quality control. A second volume is promised to cover variance analysis, experimental design, correlation, probit and discriminant analysis, and curve fitting. The book is very legibly reproduced from typescript and its price is extraordinarily low. One suggestion might very well be made: Could not future editions give the answers, or at least some of the main sums of squares and products, to lighten the burden of a teacher who sets an exercise to ten students and is presented with ten different answers?

Mr. J. Mounsey's useful little book contains about six hundred numerical exercises, but is more than a mere collection. His wealth of examples is knit together by introductory text so that the methods of calculation are explained in detail. The book is designed primarily for students in commercial and technical colleges who are preparing for examinations in statistics, and should prove very useful for that purpose. Its scope is about that of the certificate of the Royal Statistical Society—averages, index numbers, estimates of error, dispersion, lines of best fit, moments, elements of probability, binomial, Poisson and normal distributions and significance tests. There are some tables of the usual kind, and answers to the exercises are provided.

Prof. A. E. Waugh's book, now in its third edition, consists of 35 tables, a list of 137 formulae and a set of about 450 numerical exercises for class work. Many of the tables are of the standard type; but there are one or two unusual (and useful) ones, such as a perpetual Gregorian calendar and a table of the Julian day. No answers are provided, alas, but the exercises contain an abundance of stimulating material.

Teachers and students alike should be grateful for the tedious work which has gone to the making of these collections.

ZOOLOGICAL RECORD FOR 1951

The Zoological Record

Vol. 88. Being the Records of Zoological Literature relating chiefly to the Year 1951. Edited by G. Bunder Stratton. Pp. vi+592. (London: Zoological Society of London, 1953.) 120s.

THE appearance in November 1953 of the eighty-eighth volume of the "Zoological Record" is a notable achievement, for the editor and recorders have at last reduced the delay in publication, caused by the War, to less than two years, thereby much increasing the usefulness of the "Record". Some idea of the task involved may be gathered when it is considered that all zoological publications during the year in question have to be examined and the titles of papers abstracted and afterwards distributed

to the recorders for examination and classification, and then returned to the editor before going to the printers; and finally there is the proof reading involved in dealing with approximately fifteen thousand titles in many different languages.

The present volume follows the same general plan as previous ones for a number of decades and retains a somewhat artificial grouping of the animal kingdom. Thus the section *Vermes* includes such diverse groups as *Platyhelminthes*, *Nemertinea*, *Mesozoa*, *Nemathelminthes*, *Annelida* and a number of smaller classes. It might be an advantage to subdivide this section in accordance with some generally accepted scheme of modern classification, at least for the benefit of subscribers to separate sections.

The value of the "Zoological Record" to all zoologists increases with each succeeding volume, as it furnishes a more-or-less complete bibliography of the subject since its foundation in 1864. Its usefulness has been enhanced in recent years by the adoption of a general plan whereby some indication is given of the contents of each paper which are not always obvious from the title.

The list of titles, arranged alphabetically according to the name of author, is followed by a subject index in which the titles are grouped according to the particular aspects dealt with in the paper, and finally by a systematic index, in which all the species mentioned are listed according to a generally accepted scheme of classification.

The "Record" gives some indication of the work in various branches of systematic zoology in the number of titles in each of the eighteen sections into which it is subdivided. Volume 88 includes the following: comprehensive zoology, 437; Protozoa, 1,126; Porifera, 41; Coelenterata, 274; Echinodermata, 344; *Vermes*, 1,011; Brachiopoda, 211; Bryozoa (Polysoa), 56; Mollusca, 729; Crustacea, 556; Trilobita, 78; Arachnida, 666; Insecta, 1,335; Protochordata, 51; Pisces, 1,088; Amphibia and Reptilia, 1,233; Aves, 2,031; and Mammalia, 1,635. In addition, 1,813 new generic and subgeneric names were recorded in 1951. It will be seen that, as usual, the greatest number of papers deals with insects, birds and mammals occupying the next two places.

Certainly, no taxonomic zoologist can afford to be without this publication, and specialists in all branches of zoology will find it invaluable in dealing with the ever-increasing amount of literature on the subject. The title-page of the "Record" carries the words "Explore solum: sic fit via certior ultra"—a very apt quotation, for the ground is fully explored by the editor and recorders, thus making the way ahead more certain.

EDWARD HINDLE

Prof. J. R. Partington has evidently collected references on physico-chemical subjects over many years. He has read these references, noted their essential points and kept them in remembrance. He has a strong feeling for the great pioneers of the nineteenth century, and his extensive reading of earlier scientific work enables him to do them full justice, and to correct with meticulous accuracy the misconceptions and omissions of text-book writers.

Being based on collections, the book has a museum-like flavour; a museum of old-fashioned type rather than those modern ones with a few well-selected exhibits under brilliant illumination. Each worker's contribution is treated as an object to be found shelf-room. Pride of place is given to those classical subjects which can be developed with rigorous elegance from first principles. More than 130 pages are devoted to Maxwell's electromagnetic theory of light, which is followed from its beginnings to its applications to complex matters of refraction, wave-surfaces in crystals, etc. Other extensive mathematical treatments are of light scattering (50 pages), polarization of light (80 pages), dispersion (16 pages) and diffraction (15 pages). These treatments are clearly presented and, because of the author's desire to bring out the contributions of individuals, are necessarily prolonged. A valuable feature is the attention directed to the varying use of symbols by different authors. The Kerr, Faraday, Cotton and Cotton-Mouton effects are discussed more fully than in any other text-book. The chemist will be grateful for this storehouse of theory, much of which is not readily accessible. The emphasis, however, is always on the mathematical and physical side, and the chemical aspects are somewhat slightly touched on. As an example, fifty pages of highly physical theory on the scattering of light are accompanied by two pages of its applications to solutions of macro-molecules, and three pages to the Raman effect. The same physical bias is present in the treatments of artificially produced double refraction, of the interference of light, and of dichroism, while the several pages devoted to Airy's spirals and radiation pressure seem to be pure physics.

The secondary objects exhibited in the book are the numerous empirical relationships between physical properties which have been put forward by lesser scientists. The author has aimed at completeness in his record, increasing its value for reference, while diminishing it for student reading. In this field he is less insistent on mathematics. About Eyrkman's equation he says: "although it does not yet seem to have been favoured by a theoretical deduction, unlike so many formulae which are useless for practical applications, it is one which deserves to be kept in mind".

The least satisfying part of the book lies in its accounts of instruments and experimental methods. All the ways of measuring interference of light, refractive index, etc., are given with little indication of which a newcomer to research should choose. Only a superhuman scientist, of course, could combine Prof. Partington's range of knowledge in all branches of physical chemistry with an equal skill in all modern experimental techniques. The book will find a unique place in every scientific library and will be constantly consulted both by students and by research workers; all physical chemists who can afford a copy should obtain one.

E. J. BOWEN

PHYSICO-CHEMICAL OPTICS

An Advanced Treatise on Physical Chemistry

By Prof. J. R. Partington. Vol. 4: Physico-Chemical Optics. Pp. xl+668. (London: Longmans, Green and Co., Ltd., 1953.) 80s. net.

THIS fourth volume of the monumental "Advanced Treatise on Physical Chemistry", like the earlier volumes (see *Nature*, 167, 740 (1951); 169, 46 (1952); 171, 853 (1953)), fills the reader with astonishment and admiration for the encyclopaedic knowledge, historical sense, attention to detail and mathematical powers shown by the author.

Stone-worker's Progress

A Study of Stone Implements in the Pitt Rivers Museum. (Pitt Rivers Museum/University of Oxford Occasional Papers on Technology, 6.) By Sir Francis H. S. Knowles, Bart. Pp. 120. (Oxford: Pitt Rivers Museum, 1953.) 15s.

SIR FRANCIS KNOWLES, who died last year, at one time taught physical anthropology at Oxford, and it was he who studied the Mousterian teeth from Jersey and the so-called Red Lady of Paviland. About 1910 he became interested in the techniques employed by man, both prehistoric and modern, when fashioning stone implements, and the present volume is the result of this investigation. Anyone who has tried to describe shortly and clearly the various means by which flint implements can be shaped will know only too well how difficult it is to convey in words the various processes. The so-called Clacton technique is the result of a swinging blow, but, except to a specialist, what does the expression "a swinging blow" convey? Sir Francis, for example, finds himself driven to talk about "the impulsive-pressure-plus-percussion technique". Again, the "punch" technique, so important in late palaeolithic times, cannot entirely be described in a few words. Nevertheless, there is no doubt that "Stone-Worker's Progress" is a valuable book for any student to possess, for it deals with modern stone implements where the processes can be actually observed as well as with the techniques used by prehistoric man which have to be deduced. Anyone interested will knap flint himself, using the book as a guide. In this way he will understand the descriptions and learn the various possible techniques personally. The illustrations, alas, are very poor and not at all worthy of the Pitt Rivers Museum. The illustrating of flint implements is itself a specialized technique, and it is a great pity the figures were not redrawn by someone with experience in the matter. But, none the less, the volume is to be recommended to everyone who wants to know how man learnt to deal with the somewhat intractable material at his disposal. M. C. B.

Scientific Papers Presented to Max Born on his retirement from the Tait Chair of Natural Philosophy in the University of Edinburgh

Contributed by Sir Edward Appleton, David Bohm, Louis de Broglie, Richard Courant, Albert Einstein, Pascual Jordan, Th. V. Kármán and S. S. Penner, Alfred Landé, Erwin Schrödinger, Hermann Weyl. Pp. vi+94. (Edinburgh and London: Oliver and Boyd, Ltd., 1953.) 12s. 6d. net.

THIS collection of essays, presented to Prof. Max Born on his retirement from the Tait chair of natural philosophy in the University of Edinburgh, covers a wide range of subjects, from writers in widely separated parts of the world. One of Prof. Born's important early contributions to the development of the quantum theory was the introduction of the statistical interpretation of the wave function, and it is appropriate that this and related topics are the subjects of essays from several contributors—Einstein, de Broglie, Landé and Bohm—while Jordan writes on the idea of probability in genetics. Schrödinger discusses possible relations between quantum theory and general relativity, and von Kármán and Penner discuss a problem in theoretical chemical kinetics. Appleton provides the only essay in a branch of experimental physics, on geomagnetism and the ionosphere. Two essays, one by Courant on

systems of partial differential equations and one by Weyl on an analytical topic, are primarily of a pure mathematical character. Most of the essays presume some previous knowledge of their subjects, and there may not be many readers to whom these subjects will all be equally familiar; but many will find something interesting and stimulating in one or more of them. An admirable photograph of Prof. Born forms the frontispiece to the volume. D. R. H.

Statistical Design and Analysis of Experiments for Development Research

By Donald Statler Villars. Pp. xvii+455. (Dubuque, Iowa: Wm. C. Brown Company, 1951.) 6.50 dollars.

THIS book is intended to summarize, "for the busy research worker or executive", the principles of experimental design. It cannot be said to succeed. The author has tried to cover too many topics in a limited space, and understanding is further hampered by the prose style, which becomes, at times, discouragingly obscure. Nevertheless, the book has its merits: it avoids the worst excesses of the 'cook-book', despite the adoption of "a journalistic order or presentation . . . so that one may immediately start applying variance analysis to his own data", and the frequent references should greatly assist the conscientious reader.

After an elementary introduction, four chapters are devoted to experimental design and the analyses of variance and covariance; these, with supplementary chapters on "the efficiency of experimentation", "miscellaneous refinements", and the mathematics of variance analysis, comprise the bulk of the work. The discussion of the analysis of variance is generally good. Interpretation by variance components is stressed, but not followed blindly, and the circumstances in which it is appropriate are carefully described. The chapters on design are much less satisfactory. Designs of the 'split-plot' type (here called "replication degeneracy designs") are extensively discussed, and frequent warnings are given against incorrect analysis of such experiments. The section on confounding, however, contains so many mis-statements that one is led to doubt the author's own grasp of the topic, and the brief discussion of the important topic of fractional replication misses the point entirely.

Two further chapters contain short accounts of quality control and sequential methods. Extensive tables are provided. M. R. SAMPFORD

Gestation Periods

A Table and Bibliography. Third Edition. (Technical Communication No. 5 of the Commonwealth Bureau of Animal Breeding and Genetics, Edinburgh.) Compiled by J. H. Kenneth, with Additions by G. R. Ritchie. Pp. 89. (Farnham Royal, Slough: Commonwealth Agricultural Bureaux, 1953.) 7s. 6d. or 1.10 dollars.

THE appearance of a third edition of "Gestation Periods: a Table and Bibliography" in the tenth year after the publication of the first shows how much it has been in demand by naturalists, biologists and others interested in mammalian reproduction. A large number of new entries is included in this edition, many of them referring to species that had not been recorded before. Further information will no doubt be added to this most useful work with the passage of time: it includes everything recorded about the subject up to the time of going to press.

NATURAL HISTORY OF LEARNED AND SCIENTIFIC SOCIETIES

By PROF. JOHN COHEN, C. E. M. HANSEL and EDITH F. MAY

University of Manchester

OUR aim in this study is not that of the historian but is prompted rather by the question whether it is possible to detect principles, preferably quantitative, underlying the formation and growth of human associations. There are several other reasons which make the study of the growth of scientific and learned societies worth while. In the first place, it gives us a comparative measure of the development and dissemination of ideas in different branches of learning at different times. Secondly, it enables us to trace the growth of learned societies in relation to demographic, educational and technological changes. Thirdly, it provides a basis for comparing fields of interest which appear to be adequately represented by single societies with others which give rise to a diversity of groups. In the course of such inquiries matters of historical interest are bound to emerge.

Sources of Data

Our study is limited to British national societies that have survived until 1952, not with those which existed only for a time, though it would seem that the number of such is comparatively small. A list of about 220 national learned and scientific societies was compiled from three sources, "Whitaker's Almanac" for 1951, "Scientific and Learned Societies of Great Britain" (Allen and Unwin, 1951) and "The World of Learning" (Europa Publications, 1951). Nearly all the societies were included in at least two of these three sources.

Societies are described for the present purpose as learned and scientific if their aim as stated in their handbooks is to promote the study and development of a recognized branch of learning. The following types of society were excluded: those which exist solely to promote professional interests, to regulate status or to co-ordinate groups of societies for mutual support. When any of these activities is undertaken by the societies in our series, it is subsidiary to their main object of advancing some branch of learning.

A personal letter was sent to each of the societies with a request for figures of annual membership from the year of foundation onwards, the number of new members year by year, details of conditions of eligibility for membership, and references relating to the history of the society. All the leading societies and most of the smaller ones most courteously and helpfully provided adequate data. Gaps in the material were filled by consulting published records.

Birth of Societies

In the accounts given by the societies of their own origins several patterns are discernible. These patterns to some extent reflect the modes of corporate life characteristic of the period in which the society was formed. For example, in the early nineteenth century gentlemen of standing met in clubs devoted to some political, social or intellectual purpose. They enjoyed open discussion in a limited social group whose members had no need to justify their claims to membership. A society formed on this pattern at the present day would be described as a coterie.

The date when a learned society is founded is an arbitrary, if convenient, point in its history. Like the birth of a child, it marks a new phase but it is not a beginning. The society, like the infant, is first conceived and then passes through a latent phase of gestation before formal establishment.

The most common mode of generation is by the efforts of a single zealous individual. At least a third of the societies we have studied seem to have been inspired in this way. An example is the London Natural History Society, founded in 1858. That was a flourishing time for entomological societies composed of zealous collectors of specimens. As a result of a letter sent by Henry Aris to the *Weekly Intelligencer* in December 1858, the Haggerstone Entomological Society was born. The members met "at the Brownlow Arms in a spacious room over the bar, each member being provided with a long clay pipe, while the necessary refreshments were provided from below, under which soothing influences the science of Entomology was keenly pursued". In 1887 they moved to superior quarters at London Wall, abandoned pipes and pots and rechristened themselves the City of London Entomological and Natural History Society.

Another example is the Quekett Microscopical Club founded in 1865 after a proposal by Mr. W. Gibbon in a letter to *Science Gossip*. The idea found favour in the eyes of the editor, who gave it his support. Early Quekett members seem to have felt that the Royal Microscopical Society was too lofty for the amateur and looked upon the Quekett Club as a kind of preparatory school for the Royal Microscopical Society. One popular feature of the Club's activities was "Gossip Night". In 1944 the Club moved into Burlington House.

Other instances are the British Bryological Society, which owed its origin in 1896 to an advertisement by the Rev. C. H. Waddell, of Saintfield, Co. Down, proposing to set up a Moss Exchange Club; the Royal Meteorological Society, which arose out of a suggestion by J. G. Tatem in the *Monthly Magazine* in 1823 and established itself after some vicissitudes in 1850; the Royal Medico-Psychological Society, founded in 1841 by Dr. Samuel Hitch, of Gloucester, who sent a letter to all doctors in "Public Lunatic Asylums"; and the Anatomical Society, founded in 1887 on the initiative of C. B. Lockwood, a surgeon at St. Bartholomew's Hospital, London. The Anatomical Society prides itself on having accepted women members twenty-two years before the Physiological Society followed suit.

Perhaps the most illustrious member of this group is the Chemical Society, born in 1841. At that time chemistry was being taught in the medical schools, the only professional chemists being doctors or those articulated as private pupils to medical demonstrators in the schools. The man largely responsible for founding the Society was Robert Warrington, a chemist who had been articulated as a private pupil to a lecturer in a medical school. His son records that his father's task was facilitated by the introduction of the Penny Post in the previous year. The

question of admitting women members was the occasion of a long and painful struggle. Eventually a postal ballot held in 1908 yielded a result favourable to women. But the Council interpreted this to mean admission as subscribers only, and only eleven women availed themselves of the privilege.

A variant on this mode of origin is exemplified in the birth of the British Astronomical Association in 1890, from the spontaneous but independent efforts of two enthusiasts, Miss Elizabeth Brown, director of the Solar Section of the Liverpool Astronomical Society, and Mr. W. H. S. Monak, a barrister (who wrote on the subject to the *English Mechanic*). At that time there were many amateur astronomers. The Association was not intended to rival the Royal Astronomical Society but to serve those "who found the subscription to that Society too high, or the papers too technical, or who, being women, were excluded". A notable early member of the Association was a New Zealander, an "astronomical chimney-sweep", Frank Hitchens, who died in 1921, aged seventy-seven. Hitchens was a bricklayer as well as a chimney-sweep and owned a 5-in. refractor which was the largest privately owned telescope in New Zealand. He "pursued a life-long study of astronomy, and he lectured for many years; he was a fellow of the Royal Geographical Society, Canterbury Philosophical Institute, and Canterbury Microscopical Society. He was a valued contributor of records of sunspots to the B.A.A., yet his sole schooling consisted of a few weeks at a night school".

About one-sixth of the scientific societies owe their origin to a budding-off from some existing body. The Royal Astronomical Society, born in 1820, seems to have been a rebellious child of the Royal Society, and the Geological Society appears to be an offspring of the same parent. In his historical account of the Royal Society of Tropical Medicine and Hygiene, Dr. S. H. Dawkes suggested that "there would seem to be some need for contraceptive methods with regard to learned and quasi-learned societies". We must be thankful that the Royal Society did not find it necessary to employ such methods.

The Biochemical Society, born in 1911, was the offspring of a kindlier parent, the Physiological Society, five years after the launching of the *Biochemical Journal*. T. A. Gardner and R. H. A. Plimmer were leading spirits. The Society began as a club with meetings always followed by dinner, unlike the parent body, which in its youth was accustomed to meetings preceded by dinners. Doubtless this change in the sequence of activities had its beneficial effects. Meetings were irregular at first. Women were not admitted as members, and there was no president. The club became a society in 1911, the year in which it purchased the *Biochemical Journal*. In 1944 the Society initiated the Biological Council, which includes the Physiological, Anatomical, Pathological and Linnean Societies and the Society for Experimental Biology.

The Royal Statistical Society enjoyed a similar kind of birth in 1834. At the third meeting of the British Association, Quetelet wished to present some statistical material but discovered that there was no suitable section. The upshot was that a number of "noblemen and gentlemen" met later in London to establish an independent society.

The remaining half of the societies seem to have come into being: (1) to launch or support a journal; (2) to preserve a library, private laboratory, a collection of specimens left as a legacy, or dispose of

Fig. 1. Cumulative number of learned and scientific societies by date of foundation: (1) scientific societies, including general science, natural science, archaeology, sociology and anthropology; (2) the humanities; (3) medical societies; and (4) technological and agricultural societies.

some fund; (3) to enable the dying spirit of a moribund group to transmigrate into a new body; (4) as a collective effort of a group of workers already in informal contact; (5) as an expression of professional defence against hostile interests.

An example of group (1) is the Society for Experimental Biology, which was initiated by the Editorial Board of the *British Journal of Experimental Biology* in 1923 partly to find financial support for the journal.

The formation of the Scottish Marine Biological Association in 1897 illustrates group (2). Its origins may be traced to a committee set up in 1894 to take over Sir John Murray's floating laboratory at Millport. The Association has changed its name three times. Another example is the Friends of the Polar Institute, formed in 1920 with the surplus remaining from the Lord Mayor's Memorial Fund for Scott.

A representative of group (3) is the Botanical Society of the British Isles formed in 1836 and descended from the Botanical Society of London, founded by Daniel Cooper.

The Royal Society of Medicine formed in 1805 is another member of this group, although its wide scope gives it a character of its own. It was originally founded as the Medical and Chirurgical Society of London, the members of which had resented "the tenacious occupation of the Presidential Chair" of the Medical Society of London by Dr. James Sims. He had occupied it for twenty-two years. The leading figures were Dr. Marcet and Dr. Yelloly, and a Royal Charter was granted in 1834. Several attempts were made to bring the chief medical societies into a single union; but there were always societies which resisted. In 1907 eighteen societies joined and the Society assumed its present title. A distinguished society which did not enter into the 1907 amalgamation is the Royal Society of Tropical Medicine and Hygiene, and another which resisted in 1912 is the Ophthalmological Society of the United Kingdom.

* Including the following five societies formed before 1780: the Royal Society (1660), Medical Society of London (1773), the Royal Medical Society of Edinburgh (1778), the Honourable Society of Gynmrodorion (1751), Society of Antiquaries of London (1707).

† Dates of foundation of three societies in this group are not available.

The formation of the British Rheologists' Club (Society since 1951) exemplifies group (4). During the Second World War the secretary of the Institute of Physics, while visiting Dr. Scott Blair's laboratory at Reading, discovered many mutual interests, which led to the founding of a Club. Other examples are the Society for Applied Bacteriology, founded in 1934, and the Marine Biological Association of the United Kingdom. The latter was formed in 1884 by a group of influential people who met to establish a laboratory modelled on Dr. Dohrn's Station at Naples. Among those present at this meeting were T. H. Huxley, Sir John Lubbock and Sir Ray Lankester.

The Physiological Society, founded in 1876, is an example of group (5) and came into being in response to attacks on the work of physiologists. 1876 was the year in which Parliament passed the Cruelty to Animals Act to control the use of animals for experiments. The Act was provoked by opponents of these experiments, and it stimulated physiologists to band together to protect their interests. Another example of this type is the Research Defence Society, founded in 1908 to combat the four anti-vivisection societies existing about that time.

Special interest is attached to a society which illustrates the effectiveness of inbreeding by different generations from the same stock. In March 1897 the X-Ray Society was founded. Three months later it changed its title to the Röntgen Society. In 1902 the Röntgen Society gave birth to a child called the Electro-Therapeutic Society, limited to medical members. In 1905 this child abandoned its parent and joined the family of the Royal Society of Medicine. In 1917 the Electro-Therapeutic Society combined with the medical part of its true parent, the Röntgen Society, to form the British Association for the Advancement of Radiology and Physiotherapy. The Association changed its title in 1924 to the British Institute of Radiology, which finally, in 1927, amalgamated with the Röntgen Society.

There have been many other influences in the past, such as important events or publications, ease of transport and communication and facilities for printing, which have doubtless affected the origin and development of societies directly or indirectly. Among such varied influences may be included, for example, the Scientific Societies Act of 1843, the Great Exhibition of 1851 and Darwin's "The Origin of Species", 1859. Some early societies were necessarily limited to members living within a radius of thirty miles from the society's headquarters.

During the eighteenth and early nineteenth centuries novel problems thrown up by local industries stimulated much scientific activity in provincial centres. Many "little clubs or coterie of scientific and literary men" flourished. There were groups, for example, at Liverpool, Warrington, Bristol, Norwich, Manchester and Birmingham, which exerted a considerable influence on the development of scientific ideas. The Lunar Society of Birmingham, the members of which were popularly known as the "Lunatics", counted among its members Boulton, Watt, Erasmus Darwin, Wedgwood and Priestley, and "the meetings were appointed to be held monthly at the full of the moon, to enable distant members to drive home by moonlight".

Some of the Scottish societies of this period were distinguished by the conviviality of their proceedings. The Harveian Society of Edinburgh, founded in 1782, was preceded by a Faculty Club comprising a group of imaginary physicians who wore wigs and gowns at their meetings. The Society (which was for a time known as the 'Circulation') met annually on the anniversary of Harvey's birthday "to commemorate the discovery of the circulation of the blood by the circulation of the glass". Membership was limited to those proposed at the Aesculapian Club or the Dissipation Club. Dr. Andrew Duncan, the first president, in the conviction that medical men did not take sufficient exercise, established the Gymnastic Society in 1786, where Harveians were to compete with one another at swimming or other sports; but "enthusiasm for this detracted from attendance at

1900	37.0	23,100	43	536	759
1952-53	50.0	89,200	74	1,205	1,784

the Harveian Festival". Among Harveian office-bearers were a Poet Laureate and a Pontifex Maximus. Members were awarded a "Doctorate of Mirth or Merriment" in recognition of "the zest with which they joined in the festivities".

Present Position

Units of measurement. Inspection of the data suggested the use of four units of measurement, namely: (1) the number of societies founded in any period; (2) the number of societies existing at any given time; (3) the age of societies; and (4) size of membership in single societies or groups of societies.

Foundation of societies. Our data relate to national learned societies, of which 134 are scientific, technological or medical, and 77 which are concerned with the humanities. The number of societies founded in each twenty-year period since 1660 is shown in Table 1. It will be noted that the latest period relates to thirteen years only.

A word is needed to explain some of the categories in Table 2. General science includes the Royal Society, the Royal Institution, the British Association, the Scientific Film Association and the Bureau of Scientific Research. The group of biological sciences includes anatomy, physiology and psychology. Historical studies includes history of science, engineering and religion.

Number of members. The membership of each group of subjects as shown in Table 2 was obtained by adding the latest available figures of members of the individual societies; and they relate mostly to 1952-53. An individual may, of course, belong to more than one society. The group figures therefore do not indicate the number of persons. The size of seventeen societies was estimated by taking the mean of their respective groups.

Societies vary in conditions of their eligibility for membership. Some of the more specialized societies, particularly in medicine, restrict members to those having specific qualifications. For example, the British Orthopaedic Association, formed in 1918, originally required candidates for membership to submit a thesis. A few societies limit the size of the society regardless of qualifications. In other cases the limit seems to be raised as it is approached. The experience of the British Pediatric Association shows that abolition of a limit is not necessarily followed by an increase of membership.

Trends In the Growth of Scientific Societies

The main body of the present national scientific societies began to come into existence after the Napoleonic wars. In 1819 only four of the scientific societies in our series were in being. The number in existence has increased steadily since 1850. But the rate of formation of new societies does not seem to have kept pace with increase in membership of the combined societies. During the past century, membership has increased about thirteen times as com-

pared with a four- or five-fold increase in the mean membership of societies. The period since 1880 has shown a great increase in biological and medical societies. Of the sixty-eight established since that date, twenty-six are biological and twenty medical. No mathematical or chemical society has been formed during the period.

Over the past 150 years there has been a steady increase in the combined figures of membership. The increase is greater than might be expected on the basis of increase in the population of Great Britain. Figures at 50-year intervals are shown in Table 3.

The figures in the table include archaeological and anthropological societies but exclude general scientific, medical, technological and agricultural societies, which together numbered fourteen in 1850, twenty-one in 1900 and fifty-seven in 1950. The estimated totals for 1850 and 1900 are based on samples of eleven and thirty societies, respectively, out of the seventeen and forty-two in existence at those dates. The samples consisted of societies for which figures of membership at 1850 and 1900 were available.

When, however, we turn to individual scientific societies we by no means find an increase in all of them after allowance has been made for population increase. The Chemical and Physiological Societies, apart from a drop in the late thirties, have continued to increase in membership. Others, for example, the Geological and Royal Statistical Societies, display certain similarities which include, when allowance is made for population growth, an increase until 1880 and a steady and rather steep decline thereafter until about 1940.

The majority of scientific societies show a sharp rise in membership in the period 1940-50. The societies which show an increase over most of the period relative to population are best exemplified by the Chemical Society, which has continued to represent an entire field of science, in striking contrast to the proliferation of biological societies. This difference may be considered in relation to the nature of the subject-matter and the historical sequence of discoveries, on one hand, and to the stability of the societies, on the other.

Rates of growth. In order to compare the rates of growth of the different groups of sciences, a sample was taken of those societies for which complete series of figures were available. From 1880 onwards rates of increase over decades, after correcting for changes in the population of Great Britain, are shown in Fig. 2. Fluctuations are more pronounced in the early parts of the curves because of the relatively small number of societies which were rapidly increasing in size.

The rate of growth of membership must be due to many influences. The most obvious of these are increase in population and opportunities for higher education, which doubtless enlarge the potential membership of societies.

The curves may be studied in the light of developments in the different groups of sciences and of

Fig. 2. Rates of growth of scientific societies after allowing for population increase

economic and social influences. For example, the large peak in the curve of the biological societies between 1860 and 1870 may possibly be associated with the publication of "The Origin of Species" in 1859. This peak is reflected to some extent in geology and geography. In the other groups of sciences a peak of growth occurs between 1870 and 1880. There is a marked difference in the effect on membership of the First and Second World Wars, respectively. There does not appear to have been a rapid increase in membership after the first war as there was after the second.

Interpretation of the Data

The collection and analysis of our data have been guided by the idea that the development of societies might show characteristics of growth similar to those displayed by cellular colonies or human populations.

In particular, the interesting analogies between mental and physical epidemiology, which Prof. L. S. Penrose^{1,2} was the first to draw, might lead one to expect that the growth in size of learned societies over a period of time might be susceptible to analysis in epidemiological terms. He has considered crazes, panic reactions and religious enthusiasms in the light of these analogies. The societies in our series might constitute extreme members of a class of much wider range. Intermediate members of this class might be represented by cults with pretensions to scientific status which grow rapidly and decline with the advance in knowledge as, for example, the twenty-nine phrenological societies, which once enjoyed a transient existence in Great Britain. At the other extreme are the mass phenomena of the Middle Ages, such as the Flagellant Movement and dancing manias.

The brief span of life of certain societies also characterizes certain journals. "The *Glasgow Medical Examiner* made two brief but fiery appearances with one volume published in 1831, the other in 1869. Its meteoric career was characterized on both occasions by its capacity for unrestrained vituperation against all established authority and institutions, a characteristic which, along with the yellow tint of its cover, earned for it the unofficial sub-title of 'The Mustard Plaster'. Its final taunt to its more dignified rival (the *Glasgow Medical Journal*) was a description of the article appearing there as 'a mass of clotted nonsense'."

Phases in the life of scientific societies may be expressed in epidemiological terms comparable with those identified by Penrose. First there is a latent period in which the idea of a society is germinating in the minds of one or more individuals. The second phase is an increasingly rapid growth of members.

Fig. 3. Gompertz curve fitted to membership of the Geological Society

This is followed by a third phase in which the rate of growth is no longer increasing but remains fairly constant or even decreases. This may be due to exhaustion of potential membership, a factor analogous to saturation of the susceptible population in epidemiology.

During the fourth phase other influences enter, such as competing societies and shifts of scientific interest which produce immunity to the society's ideas in non-members and members alike. The development of immunity may be illustrated from the experience of one of us who joined a society about seven or eight years ago as a result of an acute 'infection' with the ideas of the society. At first the subscription was paid punctually without any prompting on the part of the society. After about three or four years, prompting was needed before the subscription was paid. At first prompting led to an immediate response. At the next stage more than one prompting became necessary and the delay became more prolonged. Eventually, the threshold of response became so high that the combined effect of several promptings was nil. There is now complete immunity.

Finally, during the fifth phase, the rate of attracting new members no longer offsets wastage from various causes. After this a society may disappear or recommence a new cycle of activity.

As might be expected, the development of learned societies seems to be subject to many more influences than is the course of an epidemic. For example, socio-economic changes and technological discoveries have a profound impact on the spread of scientific ideas and on the possibility of forming and maintaining an association.

We have fitted Gompertz curves to the figures of membership of a number of societies (without allowing for increase in population) and have found a reasonably close fit to the data. Fig. 3 shows this curve fitted to membership of the Geological Society. In the case of the Chemical Society the curve gives an excellent fit for the first eighty years of its existence. After 1920 the size of the Society fell below the expected values and at 1950 rose well above them. The curve may be used for representing stages in which a society is still growing and the size which it will reach if present conditions are maintained.

Supplementary studies and conclusion. Various independent estimates may be made of the extent of interest and development in the different fields of science in Great Britain. We have considered three types of data which could provide such estimates, namely: (1) the number of scientific journals of different kinds; (2) the number of patents sealed each year since 1852; and (3) the number of students of science in the universities.

Briefly, there seem to be two or three journals per thousand members. In the case of patents there has been a steady increase in the number sealed since 1850, comparable with the increase in membership of technological societies. During both World Wars, however, there was a distinct decline followed in each case by a recovery to the pre-war level.

The figures of university output of honours graduates in science represent perhaps the main source of potential membership of scientific societies. In 1951-52 as compared with 1925-26 the number of honours science graduates shows an increase of more than 200 per cent, advanced science students 150 per cent, and membership of societies 100 per cent.

Studies of this kind may be extended to professional, voluntary and reform societies. A special case is the growth of societies in a limited population, such as a university, where it is possible more readily to examine such problems as overlapping membership and intensity of participation. We have undertaken such an inquiry at Manchester. These studies lend themselves to elaboration on comparative lines at different levels, institutional, urban and national. For example, a comparison might be made of student life at two or more universities, or two cities might be compared with respect to the number and variety of societies of different kinds.

If size of membership of scientific societies is an index of scientific effort, the upward trend which is at present so characteristic of the figures of membership holds out promise of significant developments in the future. The trend perhaps entitles us to take a rozier view of British science in the decade ahead than recently expressed forebodings might lead one to expect.

Note. The quotations in the text are in nearly every instance taken from the literature of the societies.

INDUSTRIAL METHODS OF STERILIZATION

PROBLEMS associated with "Industrial Methods of Sterilization" were discussed on January 13 at a symposium meeting in London organized jointly by the Society for Applied Bacteriology and the Microbiology Group of the Society of Chemical Industry.

The first speaker, Dr. M. Ingram (Cambridge), discussed "Sterilization with Ozone". Ozone is widely used for air and water sterilization and for the preservation of foods, including meats and vegetables. It should be remembered that the power of penetration of ozone under such conditions is limited, and hence disinfection can take place only in the surface. The mode of action of ozone as a disinfecting agent is not understood; but it is known that it produces ozonides which in turn hydrolyse, giving rise to acid products; it also reacts with amino-acids to produce

aldehydes and hydrogen peroxide. The efficacy of disinfection is therefore dependent on the nature of the material to be treated; but exact information on the influence of various factors concerned is lacking, and much of that available is contradictory. Disinfection is not achieved in time periods of seconds, as is apparently popularly imagined, but requires several minutes. A reciprocal time-concentration relationship appears to exist, provided an initial basic concentration of about 1 p.p.m. is allowed. The presence of organic matter tends to extend the disinfecting lag-period, and a similar lag occurs where the ozone concentration is low or where surfaces are being treated.

Relative humidity plays an important part in air disinfection, for increasing values above 50 per cent result in increased activity. With solutions, the

effect of pH is difficult to measure because of the acid products of reaction, which themselves can be inhibitory to bacterial growth. Different opinions are expressed on the effect of temperature, some authors stating that it is slight or negligible, while others find that reduction of temperature below 20° C. tends to give increased efficacy. These differences may possibly be due to errors in the methods of analysis of the ozone as well as to impurities present or to products of ozone reaction. Oxides of nitrogen, for example, which can be present in large proportions depending on the method of preparing the ozone, can exert a considerable enhancement in disinfecting efficiency.

Although the popular belief is that canned foods are virtually sterile, this is not the case in practice according to Mr. Osman Jones (London), who discussed "The Survival of Bacteria in Wholesome Canned Foods". He pointed out, for example, that foods of low pH value are adequately preserved by a mild heating to kill moulds, any bacteria present being incapable of development owing to the acidity. Meat products are seldom sterile in the proper sense: up to 25 per cent of certain tinned meats have been found to contain bacteria, and Savage has put this figure, in some cases, as high as 100 per cent. Tinned meats have been kept organoleptically sound for several years, although containing viable bacteria, one of the most notable examples being that of a tin of meat brought back from the Parry Arctic expedition which, on opening after 113 years, yielded six different strains of bacteria. Pork has been inoculated with *Clostridium sporogenes* and, after heat treatment, has been stored at 37° C. for long periods without showing any deterioration, in spite of the survival of small numbers of the inoculated organisms. Sudden reactions, however, have been known to take place after relatively long periods of storage, and these may be due to slow internal reactions such as nitrite-nitrate changes. Environment affects, considerably the heat resistance of bacteria, and spore-formers are found to be more resistant in cooked meat than in raw material, and again more resistant if protected by fats. The reason why organisms should remain dormant for long periods is, at present, obscure.

Discussing the "Sterilization of Surgical Dressings", Dr. R. Maxwell Savage (London) directed particular attention to the different properties of superheated and supersaturated steams, stating that the former is inefficient as a sterilizing agent unless the temperature is raised to that for normal dry-heat sterilization. He illustrated diagrammatically how in steam autoclaves the normal sterilizing temperature and pressure could be attained either by a saturated steam cycle, as is usually carried out, or by a superheated steam cycle, in which case sterilization may not be properly achieved. Considerable care is necessary to eliminate air so far as possible as this tends to layer in the autoclave and also to give rise to 'superheated' steam, and so reduces the efficiency of sterilization. It also tends to layer around the surfaces of objects being sterilized and prevent full access of the steam. Moreover, air is always being introduced into the system via the steam mains supply, hence the need of adequate venting of the autoclave is apparent.

Contrary to expectations, dressings wrapped and sealed in paper present no difficulty in sterilizing. This is presumably because there is sufficient moisture in the dressings to provide steam to saturation point.

Similarly, dry-heat sterilization of sealed packets can be achieved more readily in closed than open packets, again due to the small amount of steam generated through the seal. Dr. Savage agreed that air-venting of dressing drums is most important, and that there are good arguments for eliminating metal containers entirely. He also thought that one effect of superheated steam is to dry off the organisms and so render them heat-resistant.

Mr. G. Sykes (Nottingham) dealt mainly with the "Sterilization of Air" as required on a large scale for antibiotic fermentations. He pointed out that sterilization by chemical means is impracticable because of the danger of the carry-over of the disinfecting material into the fermentations, and that heat treatment, although very efficient, is again impracticable on a large scale on economic grounds. Ultra-violet radiation, although suitable for many purposes, is unsuitable in this case because of its limited efficiency both in terms of time and of its inability to deal with bacterial spores and protected organisms. The precipitron, likewise, had not proved sufficiently effective in service.

Mr. Sykes then discussed the various filter materials which are commonly used in practice, and showed that both granular and fibrous materials can be used. Efficiency of filtration depends on various factors, including the size of the air-borne particles to be removed, the size of the granules or fibres of the filter, the electrostatic properties of the filter and air flow-rate, and this was demonstrated with filter materials such as alumina, glass wool, steel wool and slag wool. These findings bear out the various theories of air filtration. A coarse granule or fibre filter is less effective than a finer one, and the packing density of fibrous filters is significant; increase of air flow-rate gives a more efficient filtration. Of the various materials tested, slag wool, as previously reported by Cherry and colleagues, was found to be the most efficient. With this material at a suitable packing-density, even after prolonged continuous use, organisms have rarely penetrated beyond about 3 in.

These papers will be published in full in the *Journal of Applied Bacteriology*, copies of which are obtainable through the Society for Applied Bacteriology.

OBITUARIES

Prof. R. W. Wheldon

PROF. ROBERT WILLIAM WHELDON died on January 15, shortly after collapsing in his office in the School of Agriculture, King's College, Newcastle upon Tyne. His death is a severe loss to the University of Durham and to the many agricultural interests with which he was connected. He was widely known as a scientist, a farmer and a public servant.

Robert Wheldon was born in the county of Durham on January 17, 1893. He was a farmer's son and as such entered Armstrong College as a short-course student, having received his school education at Rutherford College. In this course, he showed his considerable ability and went on to take a degree in agriculture, graduating in 1915. He was immediately appointed by his professor, Douglas Gilchrist, to the teaching staff of the Department of Agriculture, and he afterwards served this Department, first as lec-

turer with Prof. Gilchrist and his two successors, and later as professor.

From the early age of eighteen he farmed on his own account and at the time of his death he occupied some seven hundred acres of farm-land in County Durham. Here, his pedigree herd of Jersey cattle hold an international reputation. However, his main endeavour was in the fields of agricultural teaching and research. His academic career was substantially influenced by his early training under Gilchrist, at a time when the experimental work at Cogle Park on grassland improvement was becoming world famous. As a member of the staff of the Agricultural Department, and later as director of the Cogle Park Station, he was responsible, in a very practical way, for much of the improved grassland husbandry techniques since applied to farming. His first personal contribution to agricultural research, however, was connected with the manuring of the potato crop, and he obtained his D.Sc. in 1927 as a result of this work. The period 1940-53 represents a time of considerable development of agriculture within the Newcastle Division of the University of Durham. Prof. Wheldon used all his wide knowledge and experience untiringly for the furtherance of agricultural education and research. At the beginning of the War, while still a lecturer, he was appointed acting head of the Department, and gave it fresh life. He was awarded a personal professorship in 1943 and was formally appointed as professor of agriculture and rural economy in 1947. In that year, the Department of Agriculture was enlarged to a School of Agriculture with its own faculty within the University, and with Prof. Wheldon as its first dean. In 1944, the University acquired the tenancy of a 742-acre farm at Nafferton for use as a teaching farm, and in 1945 took over Cogle Park Experimental Station from the Northumberland County Council. The numbers of students and postgraduate workers increased tenfold under Prof. Wheldon's leadership.

His skill and experience were used outside the University in the application of scientific developments to farming practice, and he played a leading part in both technical and administrative work in agriculture in the North of England. During the war period, he served with the Durham County Agricultural Executive Committee and was appointed chairman of this Committee in 1952. In addition, from September 1952 he represented the Minister of Agriculture as his personal liaison officer in the Northern Province. He undertook this work although he knew full well that by doing so he was adding to the risks of ill-health.

Prof. Wheldon was a past president of the English Jersey Cattle Breeders' Society and vice-president of the newly formed World Jersey Cattle Bureau—an organization created in no small measure by his personal efforts. His old students knew Prof. Wheldon as a great friend and an inspiring teacher. Through them, his influence on the science and practice of agriculture will go on in many ways. He was a modest man and a great Christian, who enriched the experience of all who worked with him. Above all, he will be remembered by his colleagues and friends in a very personal way, especially for his kindness and wise counsel.

J. S. HALL

Prof. H. Benndorf

DR. HANS BENNDORF, professor emeritus of physics in the University of Graz, Austria, died on February

11, 1953. He was born in 1870 at Zurich and was the son of the well-known archaeologist, Otto Benndorf. He studied mainly in Vienna, and he was appointed lecturer in the University there in 1899. During 1904-36 he was professor of physics in the University of Graz, where the Institute of Physics was, under his direction, a place of many-sided scientific investigations. Both the many students of physics and his colleagues knew him as a rigorous and critical yet kind-hearted teacher, always willing to give them assistance.

Of the scientific investigations of Benndorf, those in atmospheric electricity and seismometry are the best known and they were of great importance for further investigations. The Benndorf quadrant electrometer for registering the electrical field in the atmosphere is known throughout the world. Many other problems of pure physics, too, were dealt with at Graz under the guidance of Benndorf; for example, problems of the propagation of electrical waves, examination of luminescence and piezoelectricity, and measurements of ionization in electrical discharges. The great number of investigations at Graz directed by Benndorf was made possible by his genius for experimentation with limited resources, as there was little money in the Institute of Graz.

Benndorf's books and his theoretical papers, too, are distinguished by clarity of style, and he advised his co-workers to follow his example with regard to this. In the preface to the first volume of *Physica Acta Austriaca*, which came out in 1948 under Benndorf's stimulation, he urged young physicists to give a clear exposition of their work. Benndorf had the results of his investigations published only when he was absolutely sure of them, for he believed that physicists working in the same field should not have to study unnecessary literature.

The scientific work of Benndorf was acknowledged by his election as a member of the Academy of Sciences in Vienna in 1929.

Benndorf married his cousin, Rosa Wagner, daughter of the well-known political economist Adolf Wagner, of Berlin; they had four children. The eldest, Wolfgang, was until recently librarian in the University of Graz. His daughter Nora emigrated with her husband, a medical man, to the United States. Two of Benndorf's sons were reported missing in the Second World War.

Benndorf corresponded with many friends throughout the world and he also visited them, for he loved travelling. He was an ardent player of the viola in his leisure time, and was an excellent mountain climber. His strength of character and warmth of heart gave support and consolation to many in times of political stress.

A. SZÉKELY

We regret to announce the following deaths:

Mr. A. Campbell, one of the original members of the staff of the National Physical Laboratory, on February 6, aged ninety-one.

Prof. Kotaro Honda, formerly of the Tohoku Imperial University, known for his work on magnetism and in metallurgy, on February 12, aged eighty-three.

Mr. David Milne, C.I.E., formerly economic botanist to the Government of the Punjab, and during 1923-33 dean of the faculty of agriculture, Punjab University, Lahore, aged seventy-seven.

NEWS and VIEWS

Organic Chemistry at Belfast: Prof. R. A. Raphael

DR. RALPH ALEXANDER RAPHAEL has been appointed to the recently created professorship in organic chemistry in The Queen's University, Belfast. Part of Dr. Raphael's schooldays were spent at Wesley College, Dublin. He graduated from the Imperial College of Science and Technology, London, in 1941 with first-class honours, and was awarded the Ph.D. degree in 1943. During the years 1943-46 he took part in the Anglo-American co-operative research on penicillin, as a departmental head in the Chemotherapeutic Research Division of Messrs. May and Baker, Ltd. He returned to the Imperial College in 1946 with an Imperial Chemical Industries research fellowship, and proceeded in 1949 to Glasgow to the post he now holds as lecturer in organic chemistry. He was awarded the Meldola Medal in 1948. The main course of his research work has entailed the study of the properties of acetylenic compounds, especially in their deployment as synthetic tools for a wide range of organic compounds of biological importance. Successful syntheses during the course of this work include penicillinic acid, histamine, linoleic acid, 2-deoxyribose, and the rare branch-chain sugars, spiose and cordycepose. Dr. Raphael's devising and carrying out of numerous ingenious and original syntheses of a wide variety of near-biological compounds gives promise of much important research work in the future. His investigations have been published in some forty research publications. He is also the author of significant contributions on alicyclic chemistry to the series of text-books on the "Chemistry of Carbon Compounds", and has been occupied in researches on tropolones. The capacity Dr. Raphael has already shown of teaching organic chemistry to students and of imparting enthusiasm for research should find fresh scope in the development of the School of Chemistry at Belfast.

John Innes Horticultural Institution: New Director

DR. K. S. DODDS, who has been appointed director of the John Innes Horticultural Institution, Bayfordbury, Herts, in succession to Prof. C. D. Darlington, is a botanist with wide knowledge of economic plants and particular interests in the field of cytogenetics bearing on their evolution. After graduating at Armstrong College, University of Durham, he spent some time in Indiana State University as the holder of an Earl Grey Memorial Fellowship, and in 1937 joined the staff of the Imperial College of Tropical Agriculture in Trinidad. There he became interested in the breeding of bananas and devoted most of his research time for the next ten years to cytogenetical problems in *Musa*, with outstanding success in elucidating breeding behaviour in that complex and important group. He visited the Western Pacific on an official mission in 1945, and in 1947 was appointed professor of botany in the College, adding research on cacao and other tropical crops to his duties. Dr. Dodds left tropical agriculture in 1949 to take charge of the Commonwealth Potato Collection at Cambridge, now the Agricultural Research Council's Potato Genetics Station. At Cambridge his researches on potatoes and related species have been, like his earlier studies of bananas, chiefly directed to explaining breeding behaviour in a crop plant of complex genetical history.

American Association for the Advancement of Science: Awards

THE Prize Committee of the American Association for the Advancement of Science announced during the recent annual meeting that the twenty-sixth Newcomb Cleveland Prize of 1,000 dollars had been awarded to Prof. Barry Commoner for his paper entitled "Studies on the Biosynthesis of Tobacco Mosaic Virus". Prof. Commoner is professor of plant physiology at the Henry Shaw School of Botany, Washington University, St. Louis, Missouri, and for some years he has been studying the changes in the metabolism of tobacco leaves produced by infection with tobacco mosaic virus. His results have led him to conclude that virus formation starts from simple ammonia compounds, and that the developing virus does not incorporate amino-acids and other intermediates that already exist in cells at the time they become infected. He considers that synthesis occurs in a series of steps, and that the virus nucleic acid is made first, to be followed shortly by a range of proteins that are not identical but are all serologically related to the infective virus. Prof. Commoner and his colleagues have previously shown that tobacco mosaic virus can be prevented from multiplying in tobacco leaves by treating the leaves with thiouracil or certain other analogues of pyrimidines and purines.

The ninth Theobald Smith Award in Medical Sciences for 1953, comprising 1,000 dollars and a bronze medal, has been awarded by the Association to Dr. Irving M. London, of the College of Physicians and Surgeons, Columbia University. This award was established in 1936 by Eli Lilly and Company. Dr. London received the award in recognition of his significant contributions in the fields of porphyrin, cholesterol, and protein metabolism. He has studied the life-span of the red blood cell in normal and pathological states, such as sickle cell anaemia, polycythemia vera, and pernicious anaemia. Using isotopic tracers, he has developed a technique for the study of antibody formation in surviving tissue. This provides not only a method for studying the capacity of individual tissues to form antibodies, but also a controlled system for the study of protein synthesis *in vitro*.

Declassification of Atomic Information

As a result of the recommendations made by the sixth Tripartite Declassification Conference held at Chalk River, Canada, during April 8-10, 1953, amendments have been made to the Declassification Guide used to decide what atomic energy information may be published and what must remain secret. Dealing with reactors, a major difficulty in formulating policy has been that no sharp dividing line can be drawn between such power-producing reactors and reactors for plutonium production or military purposes, and indeed designs have been discussed for dual-purpose reactors for producing power and plutonium. It was agreed that while information of critical importance for the design or operation of reactors for plutonium production or military purposes must still be kept secret, information required for studies of the economics of power reactors should so far as possible be released. Up to the present, all work in production establishments, such as the Windscale and Capenhurst works, has been treated as classified. It has been agreed that many of the less important details and processes can now be released, while maintaining secret the production

technology of substances of critical importance to the project. However, in the case of heavy water and graphite production and the reduction of uranium compounds to metal, it has been agreed that some of the older production processes can now be declassified. All information on the neutron cross-sections of carbon and graphite has been declassified. The spontaneous fission-rate of plutonium-240 has been declassified. As a result of previous conferences, values for the thermal neutron cross-sections of uranium-235, uranium-238, natural uranium and plutonium-239 were released. It has now been agreed that the cross-sections may be published in the ordinary way, together with experimental details of the method of measurement. Much of the basic chemistry of plutonium has already been declassified. It has now been agreed that some of the physical properties that are related to the metallurgy of pure plutonium can also be released. Basic chemical studies involving the use of ion exchange resins for all elements except plutonium can be released, as can basic studies on the chemical kinetics of fluoride corrosion. Information can now be released on the production of fission products as sources of radiation for industrial and medical purposes.

Scientific Requirements of Pakistan

At the Sixth Pakistan Science Conference, held in Karachi during January 18-23, the presidential address was given by Dr. M. Raziuddin Siddiqi, vice-chancellor of the University of Peshawar, who chose as his subject "Scientific Research in the East". After referring to the fact that the early development of all sciences owed much to the scholars and savants of the East, who at the dawn of history were both leaders and sole workers in all branches of knowledge, Dr. Siddiqi affirmed that freedom of inquiry and freedom of expression are the two essential conditions for any kind of intellectual activity. Learning and scholarship thrive, he said, only where and when the true democratic spirit prevails, and the neglect of these conditions has been an important factor in the decay of scientific activity in the East during the past few centuries. Another factor has been the distortion of values and lack of appreciation of intellectual achievement: even now it is not generally recognized that education and research are as essential elements in national defence as armed forces, and that scientific education and research have their place in any long-range defence plan.

The immediate problem for Pakistan, Dr. Siddiqi continued, is not so much that of providing mechanics, technicians or science teachers as to produce the experts and research-workers of the highest standard who can discover and develop its natural resources, build up new industries, and design and instal the plant required. An intensive search for talent among students is required and, when found, the prospective experts and investigators should be given a much longer training than is at present customary. Status and remuneration also require attention, and good work in the scientific and technical field should be sure of ample recognition. Adequate provision should also be made for fundamental research, and this is a matter of equipment as well as of personnel. Apart from strengthening the research work at the universities, well-planned and equipped scientific academies and research institutes are required, and it is also desirable to remedy the failure of the existing organization for research to produce the apparatus and

equipment essential for research purposes. Dr. Siddiqi emphasized that Pakistan cannot always rely on other countries for the supply of the essential tools of research.

Plankton Studies

It is a matter of common observation that plankton is very unevenly distributed in the sea and, moreover, frequently it appears to be the case that any one patch may consist almost entirely of phytoplankton while another is mainly zooplankton. Two principal theories, not mutually exclusive, have been put forward to account for this. One, associated with the name of Harvey, is that the zooplankton would graze down a patch of phytoplankton, increasing correspondingly in numbers as it does so, until the phytoplankton is used up, and this would be followed by the dying off or migration of the zooplankton, leaving a more or less free area in which the phytoplankton could once again forge ahead. The other, associated with the name of Hardy, suggests that a high concentration of phytoplankton in some way actually repels the zooplankton and keeps it from invading the area. Richard Bainbridge (*J. Mar. Biol. Assoc.*, 32, 385; 1953) has approached the whole problem from the experimental angle. Several ingenious pieces of apparatus made of rectangular 'Perspex' tubes, including a circular channel 4 ft. in diameter with an internal diameter $2 \times 1\frac{1}{4}$ in., made it possible to follow the migration of plankton, horizontally and vertically, under controlled conditions. An arrangement of sliding water-tight doors and admission points allowed of the setting up of phytoplankton gradients and the subsequent introduction of zooplankton. On the whole, using a fairly wide range of organisms, the evidence obtained favours the 'grazing' hypothesis, but with active and directive migration, both horizontal and vertical, playing a larger part than perhaps had been envisaged previously. In initial experiments it was found that none of the diatoms used, with the possible exception of *Nitzschia* in very high concentration, showed a toxic or excluding effect.

Activity of Fungi In Dried Soil

In relation to the very considerable work now in progress both in the fields of antibiotics and plant pathology, it is essential that fungal cultures can be stored for considerable periods of time without losing their pristine physiological properties; in particular, their pathogenicity and their ability to produce particular substances under specified conditions. In a recent paper, R. G. Atkinson (*Canad. J. Bot.*, 31, 5, 542; 1953) has reviewed some of the methods which have been used for storing fungal cultures and has contributed new data on the survival and pathogenicity of *Alternaria raphani* after five years in dried soil culture. Soil cultures of *Alternaria raphani*, a seed-borne pathogen of radish, that had become dry when four to six weeks old, were still viable after five years. The incidence of residual viable centres in cultures of four of the five wild types studied was much higher than in those of their respective variants, on the basis of colony counts from platings of 5-gm. samples diluted one-fifth. The reverse of this was true for the remaining wild type and its variant. This pair was also unique in that the wild type had been shown to possess little infectivity, whereas its variant had proved to be highly virulent. The fungus showed no change in cultural characteristics after its five-year

period in dry soil, nor any loss of virulence when plants of radish, stock and wallflower were inoculated.

Royal Astronomical Society: Officers for 1954-55

At the annual general meeting of the Royal Astronomical Society, held on February 12, the following officers were elected for 1954-55: *President*, Dr. J. Jackson; *Vice-Presidents*, Miss Flora M. McBain, Prof. W. H. McCrea, Prof. H. H. Plaskett and D. H. Sadler; *Treasurer*, Prof. L. M. Milne-Thomson; *Secretaries*, Prof. C. W. Allen (University Observatory, Mill Hill Park, London, N.W.7) and Dr. A. Hunter (Royal Observatory, Greenwich); *Foreign Secretary*, Prof. F. J. M. Stratton.

Mineralogical Society of Japan: Officers

THE following have been elected officers of the Mineralogical Society of Japan. *President*: Zyunpei Harada (Hokkaido University, Sapporo); *Secretaries*: Keiichi Omori (Tohoku University); and Toshio Sudo (Tokyo University of Education). *Treasurer*: Bumpai Yoshiki (Research Laboratories of the Asahi Glass Co.). *Editors*: Nobuo Katayama (*chief editor*), Teiichi Ito, Seitaro Tsuboi and Takeo Watanabe (University of Tokyo); Zyunpei Harada (Hokkaido University); Keiichi Omori (Tohoku University); Jitsutaro Takubo (University of Kyoto); and Toyofumi Yoshimura (Kyushu University). The Society was formed at an inaugural meeting held in the University of Tokyo on June 30, 1952. Its objects are to promote the study of mineralogy and related sciences and to bring together Japanese workers engaged in mineralogical research. Two series of publications are issued as official organs of the Society: *Kobutsugaku Zasshi* (*J. Min. Soc. Japan*), of which Nos. 1, 2 and 3 were published in September 1952, January 1953 and May 1953, respectively; and *Mineralogical Journal*, first published in September 1953).

University of Birmingham

THE following have been appointed lecturers in the University of Birmingham: Dr. J. Hardwicke (experimental pathology) and Dr. J. B. Finean and Dr. W. F. R. Pover (pharmacology). The title of University Research Fellow has been conferred upon the following during the tenure of their posts as research workers in chemistry: Nadim A. Ghanem, Dr. Herbert A. Laitinen, Dr. W. G. P. Robertson, Dr. W. Brock Neeley and G. Vaughan. The following have resigned from the University: Dr. B. A. Pethica, lecturer in pharmacology, on his appointment as lecturer in the Department of Colloid Science, University of Cambridge; and G. D. Mitchell, lecturer in sociology, on his appointment as lecturer in charge of the sub-department of sociology, University College of the South-West of England, Exeter. The Gas Council has established three research scholarships, tenable for a period of three years, in the University Department of Chemical Engineering; one scholarship will be awarded each year. An expedition to the Sahara desert is being organized by Dr. E. B. Edney, reader in entomology, Department of Zoology and Comparative Anatomy, and Dr. J. Kolbuszewski, lecturer in the Department of Civil Engineering. Dr. Edney will study the ecology of desert arthropods, and Dr. Kolbuszewski will continue his studies on the wind deposition of sands. Another expedition is being made this year, the purpose of which is to study stratigraphy and paleont-

ology in west Spitsbergen, and is being organized by Mr. P. A. Garrett, lecturer in the Geology Department, in conjunction with the University College of the South-West of England, Exeter. The University of Birmingham has made grants of up to £500 to each of these two expeditions in order to defray expenses. The Huxley Lecture of the University will be given in the Chemistry Theatre, Edgbaston, at 5 p.m. on March 5, by Dr. D. M. S. Watson, formerly Jodrell professor of zoology and comparative anatomy in University College, London.

Nuffield Foundation Awards in Dentistry, Biology and the Social Sciences

THE Nuffield Foundation is offering a number of fellowships, scholarships and bursaries in the fields of dentistry, biology and social sciences as follows. The fellowships for dentistry are for persons, aged 25-35 years, with dental qualifications, to receive additional training in pure and applied science so as to undertake an academic career in dentistry, and also to enable graduates in medicine or science to receive training (not necessarily for a registrable dental qualification) that will fit them for teaching and research in dental health and disease; the fellowships are worth £500-800 a year for one to three years, and applications must be received by March 1. Dental scholarships, normally for one year only, are available for students at university dental schools in the United Kingdom and cover tuition fees and a subsistence allowance of not more than £200; applications must be received by June 30. The Foundation's scholarships and bursaries in biology and the social sciences are for graduates of British universities, preferably within the age-group 22-35 years. The awards in biology are for persons who have graduated in physics, chemistry, mathematics or engineering, but who have had no training in a biological subject, and who wish to receive such training in biology as will enable them to undertake research and teaching in the United Kingdom in biological sciences. The scholarships are for persons with some previous experience in postgraduate research in their own subject and are worth £500-800 a year (plus tuition fees); the bursaries are for those who have recently graduated and are worth £350 a year (plus fees). In both cases a marriage allowance of £50 a year and £50 for each of the first two children will be paid. Applications must be received by April 1. The awards for the social sciences are similar to those for biology, except that applications must be received by May 1 and the holder may have a degree in any subject other than the social sciences, psychology or economics; subjects suitable for study are political science, social psychology, anthropology, social statistics and sociology generally (but not economics). Application forms for all these awards and further information can be obtained from the Secretary, Nuffield Foundation, Nuffield Lodge, Regent's Park, London, N.W.1.

Semiconductors: Conference in Amsterdam

THE Netherlands Physical Society, with the support of the International Union of Pure and Applied Physics and the United Nations Educational, Scientific and Cultural Organization, is organizing an international conference on semiconductors, to be held in Amsterdam during June 29-July 3. The subjects to be discussed will include bulk recombination, surface conductivity, surface trapping, surface recombination, intermetallic compounds, the

band picture in polar and non-polar semiconductors, photoconductivity in semiconductors (such as lead sulphide, lead telluride, lead selenide, zinc sulphide and cadmium sulphide) and the application of general physical and chemical laws for the preparation of semiconductors with specific properties. During the mornings, main lectures, with time for discussion, will be given and the subjects will be considered in more detail during the afternoons, when sectional meetings will be held and brief contributions of 10-15 minutes in duration may be read. The official languages of the conference will be English, French and German. The conference is open to all, without fee, on application to the secretary, Dr. H. J. Vink, Floralaan 142, Eindhoven, from whom further information can be obtained.

Tenth International Congress of Agricultural and Food Industries, Madrid

THE Tenth International Congress of Agricultural and Food Industries, arranged under the auspices of the International Commission of Agricultural Industries, will be held in Madrid during May 30-June 6. Besides reviews and discussions of a wide variety of general problems in world agriculture, food and agricultural industries, studies will be made of a number of special, or specially processed, foodstuffs. The International Commission is an inter-governmental organization, meeting once or twice a year, the purpose of which is to study scientific, technical and economic questions directly or indirectly affecting the food, agricultural and biological industries in various countries. Its headquarters are at 18 Avenue de Villars, Paris 7°. Further information regarding the Congress in Madrid can be obtained from the General Secretary of the Tenth International Congress of Agricultural and Food Industries, Zurbano 3, Madrid.

Postgraduate Course at Salford on Chromatography

A POSTGRADUATE course on both the theory and practical aspects of chromatography will be held in the Royal Technical College, Salford, during September 13-17. The lecturers will include Drs. A. J. P. Martin and R. R. Porter (Medical Research Council), Dr. S. M. Partridge (Low Temperature Research Station, Cambridge), Mr. C. S. G. Phillips (Oxford), Dr. B. A. J. Lister (Harwell), Mr. R. A. Wells (Department of Scientific and Industrial Research), Drs. A. A. Levi and R. R. Goodall (Imperial Chemical Industries, Ltd.) and Dr. G. R. Barker (University of Manchester). The fee for the course will be £4 4s. Application forms and further information can be obtained from Dr. E. G. Edwards, Royal Technical College, Salford.

Announcements

MISS PHYLLIS BARCLAY-SMITH, secretary of the International Committee for Bird Preservation, has been awarded the Gold Medal of the Sveriges Djurskyddsföreningars Riksförbund in recognition of her work for bird protection and especially with regard to the prevention of oil pollution of the sea. The Medal was presented to her by the Swedish Ambassador on February 9.

THE Aberdeen Section and the Food and Agriculture Groups of the Society of Chemical Industry, jointly with the Scottish Branch of the Institute of Biology, will hold a conference on "New Develop-

ments in the Utilization as Food of Fish and Agricultural Products and their By-products" in Aberdeen during September 30-October 2. Details of the papers to be read and the visits which are being arranged will be published in due course.

APPLICATIONS are invited for grants from the Clough Memorial Research Fund of the Edinburgh Geological Society for geological research in Scotland and the north of England (Northumberland, Durham, Cumberland, Westmorland and Yorkshire) during April 1, 1954-March 31, 1955. The Fund was founded in 1935 for the purpose of encouraging geological research and about £30 is available annually. Applications must be sent before March 31 to the Secretary, Clough Memorial Research Fund Committee, Edinburgh Geological Society, Synod Hall, Castle Terrace, Edinburgh 1, from whom further information can be obtained.

Two scholarships, tenable at research institutions in France during the academic year 1954-55, are being offered to British workers in medical science, excluding clinical medicine, by the Medical Research Council on behalf of the Centre National de la Recherche Scientifique. They are intended for young graduates in medicine or science who have already had some experience in a branch of medical science and are worth 50,000-70,000 francs a month, with a supplementary allowance, payable in sterling, for married men. A working knowledge of the French language is essential. Application forms, to be returned by March 31, and further details can be obtained from the Secretary, Medical Research Council, 38 Old Queen Street, London, S.W.1.

THE Mond Nickel Fellowships Committee is offering a number of fellowships, open to persons of British nationality with degree or equivalent qualifications, so that they can obtain wider experience and additional training in industrial establishments, at home or abroad, in order to make them more suitable for future employment in senior technical and administrative positions in British metallurgical industries. Each fellowship will cover one full working year and will be worth £900-1,200. There are no age limits; but awards will seldom be made to persons more than thirty-five years old. Application forms, to be completed by June 1, and further information can be obtained from the secretary, Mond Nickel Fellowships Committee, 4 Grosvenor Gardens, London, S.W.1.

THE Royal Anthropological Institute has arranged six public lectures, which began on February 16 with an address by Prof. H. J. Fleure on "The English Heritage: its Study and Demonstration". The remaining five lectures will be given at fortnightly intervals on Tuesdays at 2.30 p.m. in the meeting room of the Royal Society of Arts (6 John Adam Street, London, W.C.2), the next one being on March 2. The respective subjects and speakers will be: anthropological aspects of blood-group studies in Britain (Dr. J. A. Fraser Roberts); the rural community (Prof. Adam Curle); ploughs in Britain (F. G. Paine); the importance of custom in industrial society (H. N. C. Stevenson); and the application of anthropological knowledge to our industrial society (Sir Robert Hyde). Each lecture will be followed by discussion. Admission is free. All inquiries should be directed to the Royal Anthropological Institute, 21 Bedford Square, London, W.C.1.

ELECTRON MICROSCOPY GROUP OF THE INSTITUTE OF PHYSICS

ANNUAL CONFERENCE

THE annual conference of the Electron Microscopy Group of the Institute of Physics was held in Birkbeck College, University of London, during November 10-11. The Group held its meetings in the lecture theatre of the Physics Department, and was welcomed by Prof. J. D. Bernal, head of the Department.

Papers covering the electron microscope and a wide range of its applications were read. The first paper of the conference was presented by M. E. Haine and T. Mulvey (Associated Electrical Industries, Aldermaston) on the correction of astigmatism in electron lenses. They have analysed the edge diffraction test of Hillier and Ramberg¹, showing that it is sufficiently sensitive to allow adequate correction to obtain 10 Å resolution, and they described the design and application of a four-pole cylindrical stigmator lens.

Several papers were presented covering chemical applications of electron microscopy, one of which, by E. Crampey, Dr. M. Gordon and J. W. Sharpe (Royal Technical College, Glasgow), described an electron microscope study of the hydrochlorination of natural and synthetic polyisoprene. Miss K. Little (Medical Research Council Radiobiological Research Unit, Harwell) described how the electron beam energy could manifest itself as heat and as a source of ionizing radiation, and she showed some changes in appearance of plastics which had been bombarded by electrons from a Van de Graaff generator. Miss J. M. Peckett then described a method used in the Mechanical Engineering Research Laboratory, East Kilbride, for specimen preparation of soap fibres present in alkali base greases, whereby oil is vaporized *in vacuo* to leave the soap fibres unchanged in size, shape and arrangement for viewing in the electron microscope; the specimens are used in research into the function of the structure of a grease in the lubrication of roller bearings.

Reports of work done with the reflexion electron microscope were presented by the Laboratory of Physics and Chemistry of Surfaces, University of Cambridge, and the Research Laboratories of the Associated Electrical Industries, Aldermaston. Dr. J. W. Menter and his colleagues at Cambridge described work on synthetic and other fibres, electrodeposits and the polish on diamonds, while Dr. J. F. Halliday (Aldermaston) examined the finish of surfaces prepared by typical engineering methods, such as grinding, polishing, lapping, etc., and also worn surfaces. Some advantages of the technique are that asperities making an angle of $\frac{1}{2}^\circ$ or less with the horizontal can be observed, and also the surface structures (such as electrodeposits) are more easily identifiable than by replica or light microscopical techniques.

A short note on some recent results of X-ray microscopy in the United States was presented by Dr. S. P. Newberry (General Electric Co., Schenectady, N.Y.) and Dr. W. C. Nixon (Cavendish Laboratory, Cambridge). Resolution using magnetic electron-beam focusing lenses was up to twenty times better than for electrostatic lenses. Micrographs obtained with magnetic focusing showed resolution of the order of 1 μ . Among the metal-

lurgical results an aluminium-tin alloy (5 per cent tin) 0.020 in. thick showed the deposition of tin to be along the aluminium grain-boundaries.

Dr. V. E. Coslett (chairman of the Electron Microscopy Group) and M. E. Haine (Associated Electrical Industries, Aldermaston) gave a report of the electron microscopy conference held in Innsbruck during September 16-19, 1953. This was followed by a comprehensive report by D. E. Bradley (Associated Electrical Industries, Aldermaston) on the development of a new technique for producing strong specimen-supporting membranes and also replicas of high resolution. To make the supporting films, carbon is evaporated *in vacuo* by passing a high current between two pointed carbon rods mounted so that the points are lightly held together. The evaporated carbon is allowed to fall on to the surface of glass, from which it may be stripped and mounted on specimen grids in the usual way. It may also be evaporated on to the surface of glycerol or plastic. In the latter case the plastic is dissolved away after the composite film is on the grid. To make the replicas two methods have been developed. For examining photographic grain, carbon is evaporated directly on to the emulsion, floated free on the surface of water, and mounted for the electron microscope. For metal surfaces, a plastic replica is made in the accepted manner, carbon deposited on the replicating surface, the composite replica mounted on a grid, and finally the plastic dissolved away. The carbon replica may be shadowed if desired. The carbon films produced in this way withstand the electron beam better than plastic and are more transparent to the beam. Some research done with this method was presented by J. F. Nankivell (Cavendish Laboratory, Cambridge) and E. Smith and Dr. J. Nutting (Metallurgy Laboratory, Cambridge) which supported Mr. Bradley's claim of high resolution. Dr. C. E. Challice (Wright-Fleming Institute of Microbiology, London) described how he had used the method for backing thin biological sections.

Unexpected aspects of the polystyrene-silica replica technique experienced at the Shirley Institute, Manchester, were described by S. F. Ward and Dr. D. G. Drummond. They showed that although silica, when evaporated on to the polystyrene, covers the whole surface, it remains thinner in the lee of a projection than elsewhere, producing a 'self-shadowing' effect. This effect was also shown by Mr. Bradley in his carbon replicas. A method for examining selected areas of surfaces using wet-stripped replicas was described by G. R. Booker (Metropolitan-Vickers Electrical Co., Ltd., Manchester). The selected area of surface is identified by fine scratches in the immediate vicinity, and the corresponding portion of the replica is mounted over a hole 0.015 in. in diameter in a copper disk. It is viewed in the electron microscope using a specimen screening aperture. Application of the anodic replica technique to the study of the structure of cast aluminium-manganese alloys was described by Miss M. K. B. Day (British Aluminium Co., Ltd.).

The biological session was opened by Dr. G. Eaves (School of Medicine, Leeds), who made some remarks

on the attainment of high resolution from thin tissue sections, and suggested that, to attain a resolution of 10 Å, the section must be 100 Å. or less in thickness. A short discussion followed in which Mr. Haine (Associated Electrical Industries, Aldermaston) stated that, to avoid graininess in the final photographic print due to random fluctuations in the electron beam, a 10-Å. resolution micrograph must be recorded on the photographic plate at a magnification of not less than $\times 50,000$. R. C. Valentine and Dr. J. R. G. Bradfield (University of Cambridge) then presented two papers, in the first of which they described how, by draining the suspending fluid from a drop of suspension on a collodion-covered grid, damage to bacterial cells can be minimized. In their second paper they described preliminary observations on 0.085- μ sections of *Staphylococcus aureus* and *Paracolon bacillus*. Bodies described as resembling chromosomes were shown in the nucleus, which was demonstrated to contain deoxyribonucleic acid by use of a modified Feulgen stain.

Dr. T. H. Flewett and Dr. G. Eaves (School of Medicine, Leeds) showed sections of egg membranes infected with vaccinia virus, ultra-thin sections of the vaccinia virus being demonstrated. Dr. E. M. Brieger and Dr. A. M. Glauert (Strangeways Laboratory, Cambridge) showed some sections of lung and spleen of mice infected with bovine tubercle bacillus.

Mrs. B. E. Williams reported that the National Physical Laboratory, Teddington, has developed a cheap method of producing gelatin copies of diffraction gratings, from which it is possible to make 'Formvar' replicas for the electron microscope for use in magnification calibration. The Laboratory is prepared to supply these copies at a nominal charge to cover postage and packing. C. E. CHALLICE

¹ Hillier, J., and Ramberg, H. G., *J. App. Phys.*, 18, 48 (1947).

NORTHERN SECTION OF THE PHILOSOPHY OF SCIENCE GROUP INAUGURAL MEETING

AN inaugural meeting to constitute the Northern Section of the Philosophy of Science Group of the British Society for the History of Science was held in the Staff House, University of Manchester, on January 30, at 2.30 p.m. Despite the cold weather, which made travel difficult, it was attended by representatives from the Universities of Leeds and Liverpool and the University College of North Staffordshire. Of those from the University of Manchester, eleven departments were concerned—botany, child health, classics, chemistry, extra-mural, mathematics, philosophy, psychology, radio astronomy, theoretical physics and zoology. From Leeds the departments represented were mathematics, medical physics and philosophy; from Liverpool, philosophy and zoology; and from North Staffordshire, philosophy and physics.

After Prof. L. Rosenfeld (professor of theoretical physics, University of Manchester) had been elected chairman of the business meeting, Dr. W. Mays (University of Manchester) gave an account of how the proposal for a Northern Section arose. He pointed out that for a number of years it had been felt by some members of the Philosophy of Science Group

who were living in the North of England that they were missing a good deal by not being able to attend its meetings, and it was therefore considered appropriate to have a Section of the Group in their part of the country. Such a Section would help to bring together people interested in the philosophy of science and encourage discussion and research. Inquiries made at Leeds, Liverpool, Sheffield and North Staffordshire as well as Manchester showed that there was considerable interest in the proposal. The members promoting the scheme therefore decided to ask the Philosophy of Science Group for permission to form a Northern Section, and this was readily granted. As far as future activities are concerned, it is hoped to hold meetings at regular intervals at the various university centres taking part in the scheme. There will obviously have to be a good deal of flexibility and decentralization, and, wherever possible, local centres will be encouraged to organize their own activities.

The resolution to form the Section was then put to the meeting and carried, and it was decided to elect a provisional committee to take charge of affairs until October, when there will be a general meeting and officers will be elected for the year 1954-55. Prof. D. M. Emmet (professor of philosophy, University of Manchester) was elected provisional chairman of the Section, and Dr. Mays provisional honorary secretary and treasurer. It was resolved that the committee be composed of two representatives from each University, and that members should be elected by the Philosophy of Science Group on the recommendation of the Section. Twenty-eight applications for membership were made at the meeting.

Prof. L. Rosenfeld then gave a lecture on "Rationalism in Antiquity". The topic, he said, has philosophical as well as scientific implications. If one examines the atomic theory of Democritus, one is struck by the modernness of his approach as he seriously attempts to give a rational explanation of the universe devoid of theological or mythological content. The view has been advocated that the growth of rational thinking in Ancient Greece, which led to the birth of Ionian natural philosophy, was to some extent conditioned by the social and economic changes occurring at the time. During the Pre-Socratic period the Greeks had the East opened up to them for trading purposes. In some ways one is reminded of the growth of scientific ideas during the sixteenth century as a result of navigational discoveries.

With the breakdown of Athenian democracy and its subsequent domination by Alexander, Greek philosophy lost its flexibility and became rapidly systematized. A new type of literature developed, the writing of Utopias with their veiled criticism of the authorities. The seeds sown by free discussion among the earlier Greek thinkers became, in Alexandrian times, Stoicism and Epicurianism; but whereas Democritus represented an optimistic and constructive philosophy, Epicurus and Lucretius represented a philosophy of pessimism fighting against a decaying civilization.

But the ideas of the Milesian thinkers were not entirely original. The first international carriers and merchants were the Phoenicians. If the philosophical thought of the Phoenicians was purely mythological in character, the hypothesis that there is a relationship between rationalism and commercial adventure becomes considerably weakened. The little that is

known of Phoenician cosmology would seem, however, to indicate that it too was rationalistic in character. Though this resemblance between Phoenician and Greek thought may have been solely due to their both being seafaring nations engaged in commerce, one cannot entirely rule out the possibility that the former had some influence on the latter.

W. MAYS

BRITISH GELATINE AND GLUE RESEARCH ASSOCIATION

RESEARCH PANEL MEETING

THE seventh meeting of the Research Panel of the British Gelatine and Glue Research Association was held at Beale's Restaurant, London, N.7, on November 26, with the director of research, Mr. A. G. Ward, in the chair.

The meeting took the form of a symposium on soluble collagens, the salient points under discussion being outlined in a general introduction, given by Dr. R. H. Smith (Biophysics Unit of the Medical Research Council). The remaining speakers then gave more detailed accounts of the progress made and conclusions reached in studies made using specialized techniques. Dr. R. W. G. Wykoff (science attaché to the American Embassy, London) reviewed the evidence for the conclusion that the fine structure of reconstituted collagen fibrils, as revealed by electron micrographs, depends upon the conditions for reprecipitation (for example, the pH and the precipitating agent). At present, four kinds of order may be produced, only two of which (with spacings of 640 Å. and 210 Å.) have been seen in native collagen. The remaining forms are fibrils with a spacing greater than 2000 Å. and segmented fibrils.

Dr. F. C. Kelly (Biophysics Unit of the Medical Research Council) described in some detail experiments on the production of segmented material by adding nucleotides (such as adenosine triphosphate) to solutions of alkali-soluble collagen, prepared by extracting rat skin with secondary sodium phosphate.

The preparation and properties of the materials obtained by the reconstitution of citrate-extracted calf skin, acid-extracted tendon and alkali-extracted calf skin were discussed by Dr. J. H. Bowes (British Leather Manufacturers' Research Association). Amino-acid compositions, determined by Moore and Stein's procedure, were compared with that of native ox-hide collagen. These results are of particular significance to the manufacturer of gelatine, who normally pre-treats the raw material under acid or alkaline conditions.

Dr. D. S. Jackson (Rheumatism Research Centre, Manchester) gave an account of recent work on the evaluation of the relative importance of ionic and hydrogen bonds in determining the stability of rat-tail tendon. About one-quarter of the stability appears to arise from ionic linkages between collagen and chondroitin sulphuric acid, the main mucopolysaccharide present in tendon.

An extensive investigation, using human abdominal subcutaneous connective tissue, has led to the conclusion that this tissue contains at least three acid polysaccharides, none of which is identical with chondroitin sulphate. Dr. R. Consden (Special Unit for Juvenile Rheumatism, Maidenhead) described the work leading to this conclusion, and Dr. J. E.

Eastoe (British Gelatine and Glue Research Association) mentioned that he had found similar complexity in the mucopolysaccharides in the ox-femur shaft.

The important question of how collagen fibres arise within living tissue was discussed by Dr. S. Fitton Jackson (Biophysics Unit of the Medical Research Council), who paid attention particularly to the evidence obtained from phase-contrast microscopy and electron microscopic studies on the ossification of embryonic cartilage in the chick.

The final topic for discussion was high-angle X-ray diffraction in collagen. Mr. A. O. T. North (Wheatstone Physics Laboratory, King's College, London), after indicating the difficulties associated with obtaining reconstituted collagen in a form suitable for X-ray diffraction work, discussed the information which has been obtained from diffraction diagrams of swollen rat-tail tendon. Such diagrams are typical of a helical rather than a sheet-like structure for collagen. Dr. P. M. Cowan (also of the Wheatstone Physics Laboratory) elaborated on this conclusion, mentioning the requirements of bulk density and the importance of proline residues in connexion with hydrogen-bonding and stereochemical considerations. The helical structures proposed by various authors for collagen have been examined by the optical diffraction pattern method, and none appears satisfactory.

ARAB NATIONS SCIENCE CONGRESS IN ALEXANDRIA

A SCIENCE congress for the Arab nations, arranged by the Arab Nations Organization, was held in Alexandria, for the most part in the Faculty of Commerce of the University of Alexandria, during September 1-8, 1953, under the presidency of Prof. Mostafa Naxif, vice-rector of Ibrahim University, Cairo. More than five hundred men of science attended, representing Egypt, Iraq, Jordan, Lebanon, Palestine, Saudi Arabia, Syria and Yemen. The congress was opened by the president of the Republic of Egypt, General Neguib, who, with the official delegates from the nations participating, gave short speeches in which they stressed the importance of scientific co-operation among the Arab nations.

The activities of the congress were grouped into three sections. The first section, on original researches, consisted of about sixty papers dealing with mathematics, astronomy, physics, meteorology, biology, geology and chemistry; these papers were read before three groups, each of which held four meetings. Full details of these researches will be published in a special book to be issued by the organizing committee of the congress. At the second section, on general scientific problems, the subjects discussed dealt with scientific terminology; editing, translating and publishing books; the training and equipment of science teachers for schools; and the importance of science to the national economy. The organizing committee for the congress had previously arranged for the discussion of these problems by forwarding questionnaires to members of the teaching staff in the universities and ministries of education in the participating nations, and the replies had been published in book-form and circulated to members of the congress before meeting. The Arabic language was strongly recommended for the teaching of science in universities, and encouragement of the publication

of scientific books was stressed. The third section of the congress was devoted to general cultural talks, and the subjects dealt with in this section mainly comprised the history of science in the Arab nations, such as progress in mathematical and navigational sciences, by Kazwini, Ibn El Haytham, Khawarizmi, El Tousy, El Bayrouni, El Battani, Ibn Sena, Gaber Ibn Hayan and others.

During the congress, exhibitions were arranged: one dealing with modern materials organized by the United Nations Educational, Scientific and Cultural Organization, another with the history of science in the Arab nations, and a third with scientific books written in Arabic and other languages. The congress also arranged for visits to places of scientific interest, such as the Institute of Marine Biology at Alexandria, the Roman Museum, the Misr Company for Cotton Weaving, the Misr Company for Artificial Silk, and the Burg el Arab field for desert plants. Among the decisions made in the final meeting of the congress was a recommendation for the institution of an Arab Scientific Union to be initiated by the Arab Union Organization.

WATER POLLUTION RESEARCH

REPORT FOR 1952

THE report of the Director of Water Pollution Research and that of the Water Pollution Research Board are contained in an interesting publication entitled "Water Pollution Research 1952". It is not possible in a short notice to indicate all the interesting work that is being done on this important subject, and the reports themselves should be consulted.

Work has continued on the effect of various substances on the disinfecting action of chlorine on bacteria in water, and methods have been improved for the enumeration of *Streptococcus faecalis*, an organism which is one of the indicators of faecal pollution. Work has also been done on the removal of radioactive iodine discharged as a constituent of sewage in small amounts into streams after its use in medicine.

Work on sewage at Birmingham has confirmed that slow rotation of percolating filters lowers the biochemical oxygen demand of the effluent and considerably increases its nitrification. Other work on sewage has shown that a volume of filtering medium of 10 cubic yards for each 10-20 persons gives effluents of very good quality. Experiments done in co-operation with the Gas Board have shown that spent liquor from the gasworks at Hinckley can be treated in a percolating filter in admixture with sewage, in a concentration up to 3 per cent, by volume, without causing much deterioration of the quality of the effluent. This proportion is very much higher than that possible when gas liquor of the ordinary type is used. The methods used at Hinckley for the treatment of hot gas by electrostatic precipitation, with the object of reducing the concentration of higher tar acids in the liquor, are described. Further work on this subject is in hand.

Work has also been done on industrial waste waters. In the treatment of black liquor resulting

from the kieren of cotton, an active sludge has been developed which, when it is mixed with the neutralized liquor, causes rapid anaerobic fermentation with the evolution of gas containing about 80 per cent of methane. Experiments have also been done on methods of treating simple and complex metallic cyanides mixed with sewage. It has proved possible to obtain, from sewage containing potassium, zinc and cadmium cyanides in concentrations equivalent to a hundred parts of hydrogen cyanide per million, effluents which contained an average of less than 0.2 p.p.m. of cyanide. It has also been shown that the toxicity of potassium cyanide in small concentrations increases markedly as the concentration of oxygen in solution is reduced. This is important in the design of toxicity tests and in the effect on fish of toxic substances in rivers.

The largest section of the report discusses the work on the Thames Estuary. Among the subjects studied are the distribution of salt and fresh water, the effect of rough weather in raising the level of oxygen dissolved in the water, pollution by discharges of organic matter contained in streams, sewage effluents and industrial wastes, the particle size of deposits in the Estuary, the important effect of suspended solids on the biochemical oxygen demand of Estuary water, the inhibition by oxygen of bacterial reduction of sulphate to sulphide and the catalytic effect of mud in promoting oxidation of sulphide by oxygen in solution.

The presence of large quantities of foam in rivers has been reported from many places during the year, and work on this problem is contemplated. With regard to the problem of pollution of beaches by oil, investigations on methods of preventing this pollution, in which a number of oil companies are co-operating, is in progress. A special problem, not specifically mentioned in these reports, would seem to be the general effects of substances now being extensively used for the control of pests of crops. Since the end of 1952 *Water Pollution Abstracts*, published by H.M. Stationery Office, has issued 35,000 abstracts, and the size of this monthly publication was increased in 1953 to meet the large number of papers now being written in Britain and elsewhere on this subject.

THE COSMOTRON AT THE BROOKHAVEN NATIONAL LABORATORY

VALUABLE information concerning nuclear forces and the properties of fundamental particles can be obtained from the study of the interaction of high-speed nucleons with nuclear matter and from the interaction of individual nucleons. The energies required for the production of the lighter π -mesons and the heavier mesons are known from cosmic-ray investigations, and it has been the endeavour of many workers to produce such mesons in the laboratory by means of particle accelerators. Already during 1946-47 several particle accelerators capable of producing particles with energies of 300-400 MeV., sufficient for π -mesons, were under construction; but the design of accelerators for production of the heavier mesons requiring energies of the order of 5,000 MeV. had not been investigated.

*Department of Scientific and Industrial Research. Report of the Water Pollution Research Board, with the Report of the Director of Water Pollution Research for the Year 1952. Pp. iv+64+4 plates. (London: H.M.S.O., 1953.) 2s. 6d. net.

In 1947 the Brookhaven National Laboratory, Upton, New York, after careful consideration of the scientific, economic and practical factors involved, concluded that the proton synchrotron was the best type of accelerator suitable for the purpose, and in 1948, with the financial assistance of the United States Atomic Energy Commission, the design and construction of the cosmotron was commenced. The assembly took nearly four years, and in May 1952 a proton beam of 1,000 MeV. energy was obtained. This was increased to 2,000 MeV. in the following month, and with suitable modifications to the pole windings it is confidently expected that 3,000 MeV. will finally be obtained. Machines capable of reaching higher energies are being constructed elsewhere; but the cosmotron was the first high-energy accelerator to be constructed and to be operated.

The work was directed initially by M. Stanley Livingston (Massachusetts Institute of Technology), then by Milton G. White (Princeton University), and finally by G. B. Collins, who is the present chairman and who joined the project in April 1950. A detailed description of the principle, construction and operation of the cosmotron is given in a series of articles, edited by M. Hildred Blewett, a member of the cosmotron staff, in the special cosmotron issue of the *Review of Scientific Instruments* (24, No. 9; September 1953). L. J. Haworth, director of the Brookhaven Laboratory, contributes a short foreword, and this is followed by a general review, by the editor, of the cosmotron, discussed component by component and giving data concerning the personnel, cost and basic parameters.

A ring-shaped magnet guides the particles on a circular path of radius 30 ft., and a radiofrequency electric accelerating field provides increments of energy to the protons which are injected initially into the cosmotron, at about 3.5 MeV., from a Van de Graaff accelerator. The maximum magnetic field is 14,000 gauss. The vacuum is maintained by twelve 20-in. diffusion pumps at a minimum operating pressure of 5×10^{-6} mm. of mercury, and the volume evacuated is about 300 cu. ft. The other articles in the series are divided into sections dealing with the magnet, the pole-face windings, the radio-frequency system, the injection system, the vacuum system and the control system, respectively. Finally, three short papers deal with the cosmotron building, eddy-current phenomena and studies of injection phenomena in the cosmotron, respectively.

ALEURONE LAYER IN BARLEY

IN a comprehensive anatomical investigation of the aleurone layer in the cultivated barley, J. Sawicki (*Polska Akademia Umiejętności*, No. 66, 1-59, pub. Krakow, 1952, with English summary) has examined 103 varieties, representing all the sub-species of *Hordeum sativum* collected in different parts of the world.

In these materials, the number of cell rows in the aleurone layer and its thickness were observed. The range of variability of these characters was studied to see if they could be used in the classification of barleys. The hereditary transmission of these characters was also investigated over a period of several years. It has been ascertained that the varieties examined show distinct differences in regard to both the characteristics studied. The mean number

of cell rows in the aleurone layer of the different barley varieties ranges from 1.64 to 3.11, and the mean thickness of the aleurone layer from 49.94 to 110.16 microns.

Observations of the two characteristics in question on material from several years and from different climatic conditions showed that they exhibit a comparatively small variability due to the environmental conditions. A detailed analysis of variance of material of forty varieties from 1937, 1938 and 1947 cultures showed that as regards the number of the cell rows the varietal differences are responsible for 93.00 per cent of the total variation and for 85.60 per cent as regards thickness of the aleurone layer. The variation due to seasonal differences is very small: in the first case 0.60 per cent, and in the second 0.40 per cent of the total variation. The remaining amounts of variation are due to unknown causes (environmental changes). Similar results were obtained by analysis of the variation of the pedigree lines from 1947, 1948 and 1949, indicating that there are no essential differences between the pedigree lines and the examined material of commercial varieties. The results obtained justify the view that the aleurone characters are comparatively constant and may therefore be used in classification.

It is held that the results of these investigations corroborate the earlier data of Orlov, who found that barleys endemic in the Asiatic centre of origin as a rule possess three rows, and those of the African centre two rows, of cells in the aleurone layer only. As the European varieties of cultivated barley show a similar differentiation, the possibility exists of explaining, in some cases, their primary origin.

FORESTRY COMMISSION IN SCOTLAND

IN a small illustrated pamphlet entitled "The Forestry Commission in Scotland" (recently published by the Forestry Commission) it is stated that the history of forestry in Scotland is a long one. Shakespeare in "Macbeth", for example, brought the Birnam Woods to Dunsinane, a difficult military position, and timber from the same Birnam Hill in Perthshire was used for helping the national effort during the Second World War. Great natural woods once covered most of Scotland; but through the years, fire, disease and the axe took a great toll. Later, many of the remaining forests were exploited for charcoal for iron-smelting purposes, followed by the spread of sheep-raising at the end of the eighteenth century.

It was the great inroads into the woods of the country, almost entirely privately owned, during the First World War that brought the Forestry Commission under the Forestry Act of 1919. The Commission was reconstituted by the Forestry Acts of 1945 and 1951. Under the 1945 Act the Commission was made subject to direction from the Minister of Agriculture and Fisheries and the Secretary of State for Scotland. In Scotland all land acquired through the Forestry Fund is vested in the Secretary of State.

Between the World Wars a great deal of planting was done by the Forestry Commission, but the resultant plantations were still too young to provide any contribution of value to the timber requirements of the Second World War. Once again it was the

privately owned woodlands which were subjected to over-felling, no less than 344,000 acres being felled. In Scotland this war-time felling amounted to 155,000 acres, with the result that many a glen and mountain-side are now no longer recognizable.

In 1946 the Commission embarked on a big post-war programme, the aim of which is to produce five million acres of productive forests in Great Britain. This involves the development of three million acres of new forest mainly on moorland and mountain-side and other land of low agricultural value, and the restoration to full production by private owners and the Commission of two million acres of existing woodlands. It is proposed that not less than half the new planting will be carried out in Scotland, where there is a great deal of land eminently suitable to afforestation, this being done without any interference with land which can be utilized for agriculture, for agriculture has the first call on all land.

Planting is proceeding all over Scotland at a steadily increasing rate. During the 1951-52 season nearly 31,000 acres were planted by the Commission, whereas five years before only about 12,300 were planted. By 1956 it is hoped to increase the annual rate to forty thousand acres, about 40 per cent being in the Highland counties. The Commission has one million acres of land in Scotland, three hundred thousand acres of which is planted; the balance of the land is made up of areas still being grazed and awaiting afforestation, land given up to forest nurseries, unplantable land and mountain tops the forests of which come into the national forest parks, and lastly a considerable area which will remain permanent agricultural land. Among the species of tree used, Scots pine ranks high; but on the peaty slopes of the western hills, with their high annual rainfall, Sitka and Norway spruces are more satisfactory. Other conifers used are the three larches, European, Japanese and hybrid, the Corsican pine and the Douglas fir, the latter first introduced in 1826 from British Columbia by David Douglas. The area suitable for hardwoods is limited. Already the work entailed has resulted in an increase of population, and forest villages are in the process of being built. The afforestation campaign will add in the future very considerably to the wealth of Scotland, apart from the increase in employment provided by the forests and the connected wood industries.

E. P. STEBBING

DETERMINATION OF ATOMIC MASSES BY THE PYKNO-X-RAY METHOD

By PROF. T. BATUECAS

Laboratory of Physical Chemistry, University of Santiago de Compostela, Spain

IN a previous communication¹ it was shown that the atomic masses of various chemical elements can be calculated with precision by means of the pykno-X-ray method, when the density and X-ray data of the crystalline solid have been measured at the same temperature.

It is to be noted, however, that the method as described was not capable of the highest accuracy because the data used were slightly uncertain. In order to remedy this and at the same time to check

the accuracy of the new method, researches have been in progress since 1950 in this laboratory with the object of measuring the densities of several crystalline solids at the same temperature at which their grating spaces had been determined. It seemed useful to report the first results obtained for sodium chloride, arsenic trioxide (As_2O_3 , octahedral form), and silica (α -quartz), as well as the atomic masses deduced for sodium, arsenic and silicon. Further, we can add (1) another result for the atomic mass of silicon from the very precise data obtained at 20° C. by M. E. Straumanis and E. Z. Aka² for octahedral silicon, and (2) the value for the atomic mass of calcium calculated from the excellent measurements made on calcite also at 20° C. by J. A. Bearden³.

In our calculations of 1950, we adopted calcite as reference standard "because in our opinion its density, grating space and structural geometric constant have been determined with greater accuracy than any other crystalline solid". This was qualified by the remark that "Finally, it would be better to take as reference standard instead of calcite another such as diamond. Then, of course, the value used for the Avogadro number would be that deduced from diamond". In view of the recent beautiful work on diamond of M. E. Straumanis and E. Z. Aka⁴, it seems that the time has now come for adopting as standard this latter substance instead of calcite.

Actually, using the 'methode asymetrique' (probably the most exact method available at the present time for determining the grating spaces), Straumanis and Aka have succeeded in making highly accurate measurements on three specimens of very pure diamond between 10° and 50° C. From these data the grating space at 23.5° C. (all corrections made) $d^{23.5} = (3.55961 \pm 0.00001)_A$ Å, $d^{23.5} = (3.56882 \pm 0.00008)_A \times 10^{-8}$ cm., taking into account that to convert to absolute values the values expressed in the Siegbahn scale, multiplication by the factor (1.00202 ± 0.000015) is necessary. The temperature of 23.5° C. is that at which J. A. Bearden³ determined the density of diamond which seemed then to be the most probable value, namely, $\rho_{\text{diamond}}^{23.5} = (3.51836 \pm 0.00004)$ gm./cm.³.

In our opinion, the diamond is much better than calcite as a reference standard because the uncertainty in the molecular weight of the latter is much greater than that of the atomic weight of carbon. As already stated, in taking diamond as the reference standard the value for the Avogadro number used in the calculations must necessarily be that referred to diamond. Now the unit cell of the latter contains eight atoms of carbon and the formula to be used will be:

$$8 M_{\text{diam}} = N_A \cdot \rho_{\text{diam}} \cdot (d'_{\text{diam}})^3, \quad (1)$$

in which the symbols ρ_{diam} and d'_{diam} represent in our case the density and the grating space of diamond at 23.5° C. For the atomic weight of carbon we assume $C = (12.011 \pm 0.0006)$ in agreement with that recently found in this laboratory⁵ by means of the gas dimethyl ether $(CH_3)_2O$, namely, $C = (12.011 \pm 0.001)$ and identical with the value now considered as most probable by E. Wichers⁶. On substituting the appropriate data in formula (1), the value of the Avogadro number is found to be:

$$N_A = (6.0236 \pm 0.0006)_A \times 10^{23}$$

a result used in all the calculations of atomic masses in question here.

Sodium chloride. The pycnometric measurements made by M. Carreira at 18° C. in this laboratory, using our precision technique (slightly modified), on very pure sodium chloride—fused and carefully dried beforehand—gave for the density $\rho_{\text{NaCl}}^{18} = (2.16383 \pm 0.00005)$ gm./cm.³. By taking for the grating space the value determined at 18° C. by Y. Tu³, namely, $d_{\text{NaCl}}^{18} = (5.63978 \pm 0.00003) \times 10^{-8}$ cm., and since the unit cell of sodium chloride contains four pairs of ions, the formula is

$$4 M_{\text{NaCl}} = N_A \rho_{\text{NaCl}} \cdot (d_{\text{NaCl}}^*)^3, \quad (2)$$

from which $M_{\text{NaCl}} = (58.453 \pm 0.008_4)$ and on subtraction of Cl = 35.457, the atomic weight of sodium is $22.996 \pm 0.008_4$.

Arsenic trioxide (octahedral). Starting with As₂O₃ (Merck) and after very great care in purification, M. Carreira has obtained several measurements the mean of which gives for the density at 23° C. the value $\rho^{23} = (3.8685 \pm 0.0001_4)$ gm./cm.³. By taking for the grating space the value determined, also at 23° C., by Straumanis and Ievins⁵, namely, $d' = (11.0745 \pm 0.0001) \times 10^{-8}$ cm., and applying the formula:

$$8 M_{\text{As}_2\text{O}_3} = N_A \rho_{\text{As}_2\text{O}_3} \cdot (d'_{\text{As}_2\text{O}_3})^3, \quad (3)$$

one gets for the molecular weight of As₂O₃, (395.621 ± 0.061) and for the atomic weight of arsenic:

$$\text{As} = (74.905 \pm 0.015).$$

Silica (α-quartz). Using pure transparent quartz from de Noya (La Coruna, Spain), M. Carreira has made pycnometric measurements at 18° C. by means of the same refined technique. The general means of the measurements give for the density of silica (α-quartz) the value $\rho_{\text{SiO}_2}^{18} = (2.64875 \pm 0.00008)$ gm./cm.³. For the grating space we accept the values found by A. H. Jay¹² at 18° C., namely, $a = 4.9029$ Å. and $c = 5.8933$ Å., which in absolute measure are $a' = 4.9128 \times 10^{-8}$ cm. and $c' = 5.4042 \times 10^{-8}$ cm. Assuming the unit cell of quartz, of hexagonal structure, consists of nine molecules of SiO₂, the formula becomes:

$$9 M_{\text{SiO}_2} = 3 \cdot \sqrt{\frac{8}{3}} N_A \cdot \rho_{\text{SiO}_2} \cdot a'_{\text{SiO}_2} \cdot c'_{\text{SiO}_2}, \quad (4)$$

from which the atomic weight of silicon is

$$\text{Si} = 28.076.$$

The probable errors in M_{SiO_2} and Si are not given because the uncertainty in the values of the grating space a and c measured by A. H. Jay are not known.

Silicon (octahedral). The measurements recently carried out on pure crystallized silicon by M. E. Straumanis and E. Z. Aka⁴ have fixed with high accuracy the density and grating space of this element. The values found are $\rho_{\text{Si}}^{20} = (2.3283_1 \pm 0.00031)$ gm./cm.³ and $d_{\text{Si}}^{20} = (5.41991 \pm 0.00003)$ Å., which on the absolute scale is $d'_{\text{Si}}^{20} = (5.43089 \pm 0.00011) \times 10^{-8}$ cm. Since the unit cell of silicon (octahedral) contains eight atoms, the formula is

$$8 M_{\text{Si}} = N_A \rho_{\text{Si}} (d'_{\text{Si}})^3, \quad (5)$$

from which the atomic weight of silicon is

$$\text{Si} = 28.081 \pm 0.0073.$$

In view of the calculated probable error, this figure may be regarded as in agreement with the value obtained from silica.

Calcite. The measurements on pure calcite made by Bearden and by Bearden and Shaw⁶ allow the values at 20° C. of density, grating space and geometrical structural constant to be calculated to a very high degree of accuracy. The values are $\rho^{20} = (2.71030 \pm 0.00003)$ gm./cm.³, $d^{20} = (3.03567 \pm 0.00005) \times 10^{-8}$ cm. and $\varphi(\beta) = (1.09584 \pm 0.00001)$. Since the unit cell of calcite contains four pairs of ions, the formula for the calculation of molecular weight is:

$$4 M_{\text{CaCO}_3} = N_A \cdot \rho_{\text{CaCO}_3} \cdot \varphi(\beta) \cdot (d_{\text{CaCO}_3}^*)^3, \quad (6)$$

from which $M_{\text{CaCO}_3} = (100.105 \pm 0.017_4)$, and subtracting CO₂ = 60.011 ± 0.0005, the following figure is obtained for the atomic weight of calcium:

$$\text{Ca} = (40.094 \pm 0.017).$$

These results, in our opinion, show clearly that the pykno-X-ray method, in its new form, must now be ranked as one of the methods of precision for the determination of the atomic masses of the chemical elements. It is true that the possible errors in the method can sometimes become fairly large, as is the case with calcium. At the same time, it may be emphasized that this would only be the case if, in absence of all compensation, the errors were all in the same direction and hence cumulative. Usually at least a partial compensation takes place, so that in general the errors affecting the results furnished by the pykno-X-ray method will be rather small.

INCORPORATION OF 8-AZAGUANINE INTO NUCLEIC ACIDS

By DR. ILSE LASNITZKI

Strangeways Research Laboratory, Cambridge

DR. R. E. F. MATTHEWS and DR. J. D. SMITH
Agricultural Research Council Plant Virus Research Unit,
Molteno Institute, Cambridge

8-AZAGUANINE, which differs from guanine in having the carbon atom at position 8 replaced by nitrogen, inhibits the growth of certain bacteria, fungi, algae, protozoa, animal tumours, and some plant and animal viruses. Some evidence has been presented¹ that, in certain of these cases, 8-azaguanine

can be recovered from acid hydrolysates of the ribonucleic acids, and in one instance⁴ there is indirect evidence for the presence of the compound in a nucleotide fraction. The isolation of a compound only as the free base from nucleic acids is not conclusive evidence of its incorporation, for we have frequently observed that ribonucleic acid preparations from tissues treated with 8-azaguanine, and even from viruses isolated from treated host plants, may be contaminated with small amounts of free 8-azaguanine. Only in the case of tobacco mosaic virus⁵ has it been conclusively shown, by isolation of material with the expected properties of 8-azaguanilyc acid, that 8-azaguanine is incorporated into the nucleic acid.

We have now isolated a compound with the properties of 8-azaguanilyc acid from alkaline hydrolysates of ribonucleic acids from the following after treatment with 8-azaguanine: *Bacterium coli*, *Staphylococcus aureus*, mouse liver and spleen and mouse sarcoma S 37 (in both the solid subcutaneous and the free-growing ascites forms).

B. coli strain 'B' was grown on a synthetic medium⁶ and two purine-less mutants of *B. coli* were grown on the same medium supplemented with minimal amounts of guanine. *Staph. aureus* was cultivated on a synthetic medium supplemented with small amounts of 'Marmite'. 8-Azaguanine was added to the media in concentrations between 100 and 150 µgm./ml. The bacteria were washed in 0.14 M sodium chloride, defatted and dried. Ribonucleic acid was extracted in M sodium chloride at 100°, deproteinized, and hydrolysed in N potassium hydroxide for 18 hr. at 37°.

Mice inoculated subcutaneously with sarcoma S 37 were injected intraperitoneally with two daily doses of 85 mgm. 8-azaguanine/kgm. body-weight, commencing five days after inoculation and continuing for five to seven days. Mice inoculated with sarcoma S 37 in the ascites form (where the cells grow freely suspended in the abdominal cavity) were similarly treated. Twenty-four hours after the last injection, the animals were killed, and the tumours, livers and spleens collected. In each case, livers, spleens and tumours were also taken from untreated tumour-bearing mice. 'Ribonucleoprotein' and 'deoxyribonucleoprotein' fractions were extracted from the tissues⁷. Ribonucleic acid was prepared by extraction of the 'ribonucleoprotein' fraction with M sodium chloride at 100°, partially purified and hydrolysed in N potassium hydroxide.

The methods used for the separation and identification of 8-azaguanilyc acid have already been described⁸. 8-Azaguanilyc acid isolated from alkaline hydrolysates of ribonucleic acid by paper electrophoresis at pH 9 was further characterized: (1) by chromatography in the ammonium sulphate-water solvent which separates the material into two spots corresponding to 8-azaguanosine 2' and 3' phosphates; (2) by hydrolysis in N hydrochloric acid at 100° to give a product with the chromatographic properties of 8-azaguanine; (3) by the ultra-violet absorption spectra of 8-azaguanosine 2' and 3' phosphates and the base obtained from them after acid hydrolysis. The ribonucleic acid obtained from 8-azaguanine-treated *B. coli* hydrolysed with snake venom diesterase and 5'-nucleotidase contained a substance with the expected properties of the nucleoside, 8-azaguanosine.

Table 1 gives the approximate amounts of 8-azaguanilyc acid found in the various ribonucleic acids.

Table 1. APPROXIMATE 8-AZAGUANILYC ACID CONTENTS OF RIBONUCLEIC ACIDS FROM ORGANISMS TREATED WITH 8-AZAGUANINE

Source of ribonucleic acid	Moles 8-azaguanilyc acid/100 moles ribonucleotides
<i>Bacterium coli</i>	0.2-0.5
<i>Staphylococcus aureus</i>	> 0.5
Mice bearing subcutaneous tumour (S 37)	
spleen	0.15-0.2
liver	0.2-0.4
tumour	0.05-0.1
Mice bearing ascites tumour (S 37)	
liver	none detected
tumour	0.15-0.2

With the purine-requiring mutants of *B. coli*, increasing the amount of guanine in the medium considerably decreased the incorporation of 8-azaguanine. We have confirmed that 8-azaguanine inhibits the growth of *B. coli*.

Although a substantial amount of 8-azaguanilyc acid was isolated from the liver ribonucleic acid from animals bearing subcutaneous tumours, none could be detected in liver ribonucleic acid from animals with ascites tumours (Table 1). Possibly the flow of lymph into the abdominal cavity which accompanies the development of the ascites tumours restricts the absorption of 8-azaguanine into the general circulation. The higher 8-azaguanine content of ribonucleic acid from ascites tumour cells compared with that from subcutaneous tumour cells is presumably due to the ascites tumour cells being in direct contact with much higher concentrations of the compound.

Treatment of animals bearing the subcutaneous form of the S 37 sarcoma with 8-azaguanine resulted in a delay of tumour growth, particularly during the first days of treatment. Livers and spleens from the treated animals showed no macroscopic changes, and histological examination revealed no signs of degeneration.

Tumours developed in all five control animals inoculated with the ascites form of S 37, but only in four out of the seven animals treated with 8-azaguanine. In these the mitotic rate of the tumour cells was reduced and the final volume of tumour cells per animal was about 40 per cent that of the controls.

Evidence has been given that particles of tobacco mosaic virus containing 8-azaguanine incorporated into their ribonucleic acid are non-infectious⁹, so it seems likely that the growth inhibition in bacteria and animal tissues may be largely due to the synthesis of biologically inactive ribonucleic acid containing 8-azaguanine. The results of Carlo and Mandel¹⁰ would not be inconsistent with this view. They found that 8-azaguanine had no significant effect on the incorporation of carbon-14 labelled guanine or 4-amino-5-imidazolecarboxamide into the nucleic acids of liver or sarcoma S 37 of mice. Any compound such as the riboside or nucleotide of 8-azaguanine which might be incorporated more readily than 8-azaguanine itself into ribonucleic acids will be of interest, particularly in systems such as tumours and viruses where growth inhibition is a desirable end.

We have attempted to detect 8-azaguanine in the deoxyribonucleic acid of liver, spleen and the tumours from mice treated with 8-azaguanine, and in that of *B. coli* 'B' and its bacteriophage T₂⁺ grown in the presence of 8-azaguanine. The purines were liberated from deoxyribonucleic acid by hydrolysis in N hydrochloric acid at 50° and separated by chromatographic and paper electrophoretic techniques which would

have allowed the easy detection of 8-azaguanine. In no case was this observed.

While we cannot exclude the possibility that the 8-azaguanine may be incorporated into deoxyribonucleic acid in amounts too small to be detected by our methods, there are structural considerations which may make its incorporation unlikely. In the Watson and Crick⁴ model of deoxyribonucleic acid, the keto form of the 6(OH) group of guanine forms an essential part of the hydrogen-bonded structure. The pK of the 6(OH) group in 8-azaguanine is 2-3 pH units below that of guanine⁵, so that at physiological pH values the percentage of molecules not in the keto form would be considerable. [Dec. 10.]

ESTIMATION OF ZINC IN BIOLOGICAL SPECIMENS

Determination of Zinc-65

THERE is evidence that zinc is necessary for animals and plants; but information about the physiological role of this metal is scant. The enzyme carbonic anhydrase, present in red blood cells and certain other tissues, contains zinc as an integral part of the protein molecule¹; but little is known about the way in which zinc is combined in other animal tissues. In recent years considerable interest has been shown in the distribution of this metal in various tissues. It has been shown, for example, that human leucocytes contain two zinc-containing protein complexes², that some of the zinc in tumour tissue is loosely bound to nucleoprotein in the cell nuclei³, and that zinc in egg yolk is firmly bound to the protein part (vitellin) of lipovitellin⁴.

The use of a radioactive isotope of zinc (⁶⁵Zn) has greatly facilitated recent studies on zinc metabolism, and when radioactive zinc of high specific activity becomes more generally available, it is expected that there will be an increasing need for comparatively simple methods for measuring the amount of zinc-65 in tissues. In our own investigations we are using three different methods, and the following brief outline of these methods may be helpful to others who contemplate using it for biological investigations. A more complete account will be given elsewhere.

(1) *Quick, wet combustion method.* This method, a simplified version of method (2), involves the heating of a weighed amount of the tissue (for example, 0.1-5 gm.) with concentrated nitric acid or concentrated sulphuric acid (2 ml. per gm., with a minimum of 1 ml.) until a clear solution is obtained. When sulphuric acid is used, selenium dioxide (about 5 mgm. per ml.) should be added as a catalyst, and the digest can then be used for a total nitrogen determination. (Sulphuric acid has a further advantage over nitric acid in this respect, for acid fumes from the diluted nitric acid digest may cause corrosion of the counting equipment.) The acid digest is diluted

with water to a standard volume (for example, 15 or 20 ml.) and the radioactivity of 10 ml. of this solution is measured in a Veall-type⁵ counter for liquids.

We have found that under these conditions no correction for self-absorption is normally required, and the method gives complete recovery of zinc-65 added (as zinc chloride) to animal tissues or present in the tissues of animals previously injected with the isotope.

(2) *Extraction method.* Where there is a possibility that the material to be analysed contains significant amounts of radioactive isotopes other than zinc-65, some method of extracting the zinc from the digested tissue should be adopted. The tissue should be completely digested by long heating with an acid mixture, ammonia added to bring to pH 8.5-9.0, and the solution repeatedly shaken with a solution of dithizone in carbon tetrachloride to extract the zinc. The zinc in this zinc-dithizone solution is then extracted by dilute hydrochloric acid, and the radioactivity of this acid solution measured directly in a Veall-type counter.

This method is laborious, and it involves considerable manipulation and transference of solutions, with a loss of 3-5 per cent of the zinc-65.

(3) *Scintillation counter method.* Recently we have been using a scintillation counter for measuring the amount of zinc-65 in tissues, and, as we had expected (mainly from consideration of the decay scheme of zinc-65), this method proved to have several advantages over those which involve the use of a Geiger counter. Since the scintillation counter measurements are entirely concerned with the γ -radiation of this isotope, the preparation of the tissue for the determination is simple. Radioactivity measurements can be made on the homogenized tissue or on the solution obtained by heating the tissue with sulphuric acid as in method (1), and no self-absorption correction is required.

Table 1 gives a few typical results obtained with tissues (mouse liver and mammary gland) to which zinc-65 had been added (as zinc chloride) or which had been removed from mice previously injected with the isotope. In these particular experiments the tissues were first subjected to short acid digestion, to permit comparable determinations to be made with a Geiger counter, and scintillation counter measurements were made on 3-5 ml. of the diluted digest.

The results of these and many similar experiments have shown that for zinc-65 determinations the scintillation counter has a much greater sensitivity and consistency than has the Geiger counter. Furthermore, long acid digestion of the tissue is not required. Recently, we have found the scintillation counter method most helpful for determinations of the zinc-65 content of the faeces of hens which have been injected with the isotope, for direct measurements

Table 1. COMPARATIVE COUNT-RATES FOR ZINC-65 IN ANIMAL TISSUES WHEN MEASURED WITH SCINTILLATION COUNTERS (SC) AND GEIGER-MÜLLER COUNTERS (GC) FOR LIQUIDS (TYPE M6)

Tissue (No.)	Gross count-rate (counts per min.)		Background count-rate (counts per min.)		Ratio (net count-rate of sample/background count-rate)	
	SC	GC	SC	GC	SC	GC
1	28,200	1,008	209	18	90	55
2	7,500	228	315	15	23.6	18.9
3	1,290	57	322	16	8.0	2.6
4	512	23	315	16	0.6	0.4

can be made on the homogenized faeces. Wherever cross-checks have been made, the results obtained with the scintillation counter have been identical with those obtained with methods (1) and (2) above.

These investigations have been carried out with the aid of grants from the British Empire Cancer Campaign and the Medical Research Council, and we are also indebted to Prof. P. B. Moon and Prof. W. E. Burcham for the arrangements under which we were able to obtain irradiated copper target bars from the Birmingham cyclotron. The activated sodium iodide crystal used for the scintillation counter was supplied by the Atomic Energy Research Establishment, Harwell, and we are grateful to Dr. Denis Taylor and Mr. R. B. Owen for their help in this matter.

Separation of Radioactive Zinc from Cyclotron-Irradiated Copper

THE chemical separation of radioactive zinc of very high specific activity from cyclotron-irradiated copper usually presents considerable practical difficulties on account of the minute amounts of total zinc which have to be separated from relatively large amounts of copper.

In the method described here, the irradiated copper target, which has usually been plated with spectrum-pure copper before irradiation, is arranged as the anode of an electrolytic cell containing 100 ml. of dilute sulphuric acid (about 4 N). Any parts of the surface of the target which are not to be brought into solution are protected by a coat of varnish. A copper-foil cathode is used, and a potential difference of 1 volt is applied. Electrolysis is continued until almost all the zinc-65 has been removed from the target, the solution in the cell being changed several times during this process. Each radioactive solution obtained is evaporated to dryness and the residue dissolved in an *n*-butanol-hydrochloric acid mixture (96 volumes of redistilled *n*-butanol to 4 volumes of constant-boiling hydrochloric acid). This solution is transferred to a cellulose-powder chromatography column (Whatman's ashless filter-paper powder), and the metals eluted with the same solvent mixture. Under these conditions, zinc moves rapidly down the column and is completely eluted before the visible green band, due to cupric chloride, approaches the bottom of the column. The radioactive eluates from each electrolysis fraction are pooled and the solvents

Fig. 1. Chromatographic separation of zinc-65 from irradiated copper (cellulose powder column 10 m. long and 1 in. diameter)

removed by distillation under reduced pressure. The residue is dissolved in a small volume (5-10 ml.) of constant-boiling hydrochloric acid. Copper cannot be detected in this final acid solution by a spot test depending upon the catalytic action of cupric ions on decomposition of the ferric iron-thiosulphate-complex ion¹. This reaction will detect 0.02 µgm. copper at a minimum concentration of 1 part in 2,500,000. The fractions obtained from the surface of the target do not contain sufficiently large amounts of zinc to be detectable by the formation of zinc mercuric thiocyanate in a spot test¹ (sensitivity: 0.2-0.5 µgm. zinc at a minimum concentration of 1 part in 100,000). The fractions obtained from the deeper parts of the target contain small (microgram) amounts of carrier zinc, which may be derived from non-radioactive zinc originally present as an impurity in this part of the target. It has been shown that, under the conditions of these separations, the cellulose powder and reagents do not contribute detectable amounts of zinc to the product.

An example of the recovery of radioactive zinc in serial 10-ml. fractions of the eluate is shown in Fig. 1. The relatively large volume of the solutions chromatographed has necessitated the use of larger columns than those recommended for the chromatographic separation of metals in analytical work². Good results have been obtained with cellulose columns 10 in. long and 1 in. in diameter, and with columns 14 in. long and 1½ in. in diameter.

We are indebted to Prof. A. Wormall for his interest and encouragement, and to the British Empire Cancer Campaign for financial support. The irradiations were performed in the University of Birmingham cyclotron through the courtesy of Profs. P. B. Moon and W. E. Burcham.

Ultra-Violet Irradiation of Tobacco Infected with Potato Virus Y and the Availability of Virus to Aphids

SINCE many workers in widely divergent fields are interested in the biological effects of ionizing radiations, new methods of approach to this study may have wider application than is at first realized. This communication reports that ultra-violet irradiation of tobacco infected with potato virus Y can reduce the availability of virus to aphids without causing apparent injury to the plants or greatly reducing the infectivity of sap extracts as measured by starch-iodine lesions.

Leaves of White Burley (*Nicotiana tabacum* L.) tobacco plants showing well-developed symptoms of infection with potato virus Y were irradiated in the dark 15 cm. from a source of ultra-violet light. (The intensity of radiation of 2537 Å. on the surface of the leaves was about 2 mW. per sq. cm.) Half of each leaf was either removed or covered during irradiation to serve as an unirradiated control. After irradiation, the plants were placed in daylight under glass for several hours, and then kept under normal glasshouse conditions of illumination. The availability of virus to aphids was tested with fasted wingless adults of *Myzus persicae* (Sulz.), which were transferred in pairs from the source of infection to young healthy tobacco plants for 24 hr.

When aphids spent two minutes on the leaves immediately after irradiation, the pairs out of 70 that transmitted from leaves irradiated zero, two, four and eight minutes were 68, 28, 11 and 1 respectively. Many fewer transmissions resulted when the aphids spent four hours on the leaves; but the differences in the numbers of transmissions from irradiated and unirradiated leaves were similar to those above. Irradiation of one surface of a leaf did not affect the availability of virus from the other; nor did irradiation appear to affect the feeding behaviour of the aphids. The irradiated plants continued to grow and looked the same as the controls, and the availability of virus to aphids returned to normal within a few days. For example, after two to four days, as many transmissions were obtained from leaves irradiated two minutes as from the controls, and transmissions from leaves irradiated five minutes equalled that of the controls after five to ten days.

Ultra-violet irradiation of some plant viruses *in vitro* results in a loss of infectivity without any gross changes in their physicochemical properties¹ and, by analogy, virus infectivity is probably destroyed *in vivo* when infected plants are irradiated. Although detailed infectivity tests have not yet been done, the following tests indicate that if ultra-violet destroys infectivity *in vivo*, then only a small part of the total virus in a leaf is so affected during the brief periods of irradiation required nearly completely to reduce the availability of virus to *M. persicae*. Infected leaves were divided along the mid-veins, and one-half of each leaf was irradiated for five minutes, the other half serving as an untreated control. The pairs of aphids out of 20 that transmitted virus after two minutes on these leaves were zero for the irradiated

and 18 for the controls. Sap expressed from each group of half-leaves and diluted with an equal volume of phosphate buffer at pH 7 was inoculated on opposite half-leaves of tobacco. Sap from the irradiated leaves produced as many starch-iodine lesions² as that from the controls in one experiment; when repeated, however, slightly fewer lesions were produced by sap from the irradiated leaves, the difference being less than 10 per cent.

M. persicae becomes infective with potato virus Y during feeding punctures when the stylets are inserted into the epidermis of infected plants, and transmission rarely, if ever, occurs after the stylets have penetrated into deeper tissues³. Therefore, it is only necessary to postulate inactivation of potato virus Y in the epidermis of the irradiated tobacco leaves to account for the results reported here.

Protein Synthesis and Genetics

THE recent exchange of views in *Nature* regarding the biosynthesis of proteins prompts some comments from a geneticist. Campbell and Work¹ take note of "the two main streams of thought on protein synthesis: one derived from the study of isolated enzyme systems and suggesting a stepwise coupling of many small peptide units; the other based on the study of genetic inheritance of protein specificity and preferring synthesis on templates, each template being specific for a single protein structure and probably identifiable with a gene". While not rejecting the latter view (one gene-one protein), they point to some of the difficulties with which it is confronted, and further suggest the possibility that a synthesis of the two ideas will be found to fit the facts. Dounce², on the other hand, elaborates and defends a nucleic acid template hypothesis, and suggests that such a hypothesis is consistent with the existence of both plasma genes and nuclear genes. Quite independently, immunogenetic and biochemical studies of controllable genetic material have yielded results suggesting a synthesis of these views.

In *Drosophila melanogaster*, genic interaction has been demonstrated in the determination of antigenic specificity, a finding difficult to reconcile with the one gene-one protein hypothesis. In one series of isogenic stocks, interaction between at least three non-allelic loci is responsible for the presence or absence of a particular antigenic component. Two of these loci have been identified (ruby and vermilion), and have morphological as well as antigenic effects³. In another series of isogenic stocks, interaction between alleles results in a distinctive antigenic component in heterozygotes. The interaction involves the wild and mutant alleles at the loci

for lozenge *BS* and/or lozenge-46⁴, which are also notable for their pseudoallelism⁵. In the former case the interaction antigen is undoubtedly protein⁶, and in the latter case it is probably protein. The patterns of interaction in these cases are such as to suggest that protein synthesis occurs in two gene-controlled stages: a series of preliminary steps leading to the production of non-specific precursors, and a second stage during which final specificity is conferred upon the product.

In *Neurospora crassa*, the genetic control of the enzyme tyrosinase in strain 15300 (albino-2) has been subjected to intensive investigation. Only a preliminary report has been published⁷ and the analysis is not yet complete, but available results are suggestive enough to deserve comment. The enzymatic activity of homogenates of cultures grown under standardized conditions has been measured with two substrates, tyrosine and 3,4-dihydroxyphenylalanine. As has been reported, the two mating types of strain 15300 differ in tyrosinase activity, mating type *a* exhibiting high activity and *A* exhibiting no measurable activity. Single ascospore cultures isolated from the crosses 15300*A* × 15300*a* also exhibit differences in tyrosinase activity, ranging from activities as low as that of 15300*A* to activities higher than that of 15300*a*, and varying independently of mating type. The distribution of activities among cultures of the progeny suggests multiple factorial inheritance. Since the differences in activity cannot be attributed to extraneous factors such as inhibition, the simplest interpretation of these results is that the level of enzyme concentration in this strain is controlled by a multiple genic system. Completion of the genetic analysis of this situation has awaited the development of suitable genetic methods⁸, and is now under way.

The specificity of the enzyme, as measured in terms of its relative activity with the two substrates, also varies among the cultures, but independently of level of activity. The inheritance of this difference is again not simple; but the data suggest one locus with a major effect on specificity and several with smaller effects. This situation is also being investigated further.

Tentative as they are, these results nevertheless suggest a duality in the genetic control of tyrosinase synthesis. One genetic system seems to control enzyme concentration, and a second seems to control enzyme specificity. Such duality suggests in turn a two-stage process in enzyme synthesis: a preliminary stage involving the synthesis of non-specific precursor (protyrosinase) under the control of one genetic system, and the conversion of precursor to enzyme (tyrosinase) under the control of a second system. Quantitative aspects of enzyme synthesis could involve the first stage, and specificity could be conferred during the second. This hypothesis has led to the demonstration of protyrosinase in this material. The kinetics of its development and the mechanism of its conversion to active enzyme are being studied.

The similarity of the conclusions drawn from the two aspects of this work, that with *Drosophila* and that with *Neurospora*, is notable. In connexion with the previous discussion in *Nature*, it might be suggested that the synthesis of non-specific precursor occurs in a stepwise fashion, while specificity is the function of template action. If this is the case, the gene-template relationship cannot be simple, as judged from our *Neurospora* data, and perhaps the

template itself is synthesized by a similar two-stage process. The genetic control of protein synthesis would in any event be indirect and complex, perhaps approaching the level of complexity of the genetic control of morphogenesis.

Such an epigenetic point of view leads one to expect environmental-cytoplasmic-nuclear interactions in protein synthesis, and it is therefore interesting to note that the *Neurospora* tyrosinase appears to be adaptive. The genetic analysis is therefore performed with material grown in the presence of substrate (tyrosine); but the observation of enzyme adaptation suggests a cytoplasmic mechanism which is triggered by environmental factors and which interacts with the nucleus, such as has been discussed by other workers⁹.

I wish to acknowledge the contributions made to this work by Mr. V. Feldmiller, Mr. R. O. Wolf, Dr. A. Chovnick and Dr. S. Koritz. The work itself was supported by research grants from the National Institutes of Health and performed at the Ohio State University.

Culture *in vitro* of Cambial Tissue of Cacao

DURING work on the physiology of rooting cacao cuttings, attempts were made to induce the formation of roots on isolated stem sections in sterile culture. Although no differentiation was obtained, the profuse growth of callus tissue at the morphological base of the section suggested that cacao would be a suitable subject for tissue-culture investigations.

Further experiments showed that isolates of bark similar to bud 'shields' could be cultured successfully on a simple solid medium, such as that used by Gautheret¹ for his initial isolations. These cultures produced sufficient cambial tissue in two to three months for subcultures to be made; growth of the new tissue was visible after 24 hr. No external source of growth substance was found to be necessary for growth.

The nutritional requirements of the sub-cultures, consisting of cambial tissue only, were more complex than those of the original isolates. White's standard formula² supported only very slow growth. Spectacular increases in the growth-rates were obtained, however, with the addition of coconut milk in varying concentrations to White's medium. The highest rate of growth was given on a medium of pure coconut milk. The subcultures were grown on liquid medium by a method similar to that described by Stokes³ for

embryo-culture. Initial isolates did not grow as well using the liquid method of culture as on a solid medium.

No external source of growth substance was employed with those media containing coconut milk. Subcultures grown on White's medium alone showed no response to the addition of low concentrations of growth substance, and higher concentrations, of the order of 10^{-4} , caused considerable losses.

Isolates from plants infected with 'swollen shoot' virus have also been cultured successfully. Eight to ten successive subcultures have been made from isolates from such infected plants. It has not yet been possible to demonstrate the presence of the virus in the isolates or in the newly formed tissues. This may be largely because of the limitations imposed by the available methods of testing for the virus. The nutritional requirements of the 'infected' cultures are similar to those of healthy tissues, and the growth-rates are similar. Histological examination of these tissues has so far shown no differences from healthy tissues.

Referring particularly to the tissue of *Vitis*, Gautheret¹ suggests that the physiology of this tissue is so greatly changed, when cultured upon a medium containing coconut milk, as to bear no relation to that of normal tissue, and that the intense proliferation of the tissue is often of a pathological nature.

The tissue produced upon explants from cacao is normally compact, white and granular. When subcultured upon White's standard medium with pantothenic acid and biotin, the newly formed tissues present a similar appearance. No growth takes place at the point of contact of the culture with the medium, whether the latter be liquid or solid. When subcultured upon a medium containing coconut milk, however, the morphology of the tissue is greatly changed. Further, there is a considerable difference between tissues cultured on solid media and those on liquid.

On agar slopes, the typical white mass of tissue is gradually overgrown by a disorganized, loosely granular tissue, which is pale brown in colour and translucent. The growth is rapid compared with that on the standard medium. The subcultures retain this appearance. When subcultured on liquid coconut milk by Stokes's² method, the change in the morphology of the tissue is even more marked. Proliferation takes place only at those points of the culture in contact with the medium-soaked filter paper. The original tissue is raised from the surface of the paper by one or more masses of new tissue. The latter, while still pale brown and translucent, is compact but extremely soft and 'mushy'. The original culture ultimately dies. Further subculture of the new tissue is made easy by the fact that all the cells composing it seem capable of division; it is so soft that a smear of the tissue across the surface of the filter paper support will, in the course of a month, give rise to masses of tissue large enough for further subculture.

After about four subcultures on coconut milk, in some cases a further change in the morphology of the cultures is noticeable. The tissue becomes practically colourless, and of a much more granular and solid nature. This form is maintained in succeeding subcultures. The differences in morphology of those cultures grown on agar slopes containing coconut milk, compared with those grown on a liquid medium, are probably due to the greater avail-

ability of nutrients, growth substances and the so-called 'coconut milk factor' in the latter.

I wish to thank the Director of Cacao Research, West African Cacao Research Institute, for permission to publish this communication. A full report of the work will be given later.

Occurrence of Endosperm Haustoria in some Cucurbitaceae

THE embryology and seed structure of the Cucurbitaceae have attracted much attention, and a good deal of work has been done by Longo, Kirkwood, Kratzer, Singh, and others¹, most of it based on a study of sections. However, sections often fail to give a three-dimensional picture of an organ, and occasionally even simple structures are ignored or overlooked. In my work I used both sections and dissections, and observed characteristic endosperm haustoria in several members of this family, which have not been reported earlier.

Species of the following genera were investigated: *Trichosanthes*, *Lagenaria*, *Luffa*, *Momordica*, *Cucumis*, *Citrullus*, *Coccinia*, *Ocucurbita*, *Melothria*, *Blastaria* and *Actinostemma*. All these except *Blastaria* were found to possess a chalazal endosperm oecum. A comparative account of the endosperm of *Momordica*, *Trichosanthes*, *Luffa* and *Lagenaria* is presented below.

The endosperm is of the nuclear type. Soon after fertilization, the embryo-sac elongates (Fig. 1) and its upper part broadens while the lower remains narrow. Wall formation occurs only in the former. It is simultaneous in *Lagenaria*, *Luffa* and *Trichosanthes*, whereas in *Momordica* it progresses from the apex downwards (Figs. 2, 3, 4). The chalazal end, which is oocytic, forms a tubular process (Figs. 4, 10) which soon becomes worm-like in *Trichosanthes* (Fig. 6) and assumes a shape similar to that of the 'vermiform appendage' of some members of the Proteaceae². Frequently, the nuclei present in the chalazal process are larger than those in the upper cellular part (Figs. 4, 11).

The maximum length attained by the appendage varies from 700 μ in *Momordica* to more than 6,000 μ in *Trichosanthes*. The haustorium shows dense granular cytoplasm with many free nuclei (Figs. 4, 7, 11) which often aggregate in groups of 3-7. The nucellar cells around the appendage present a furnished appearance and gradually their walls break down.

The cellular part of the endosperm increases greatly in size by cell divisions and cell enlargement. The nuclei of the centrally situated cells become markedly hypertrophied and irregular in outline. In the basal portion the outer cells bulge out prominently, this feature being specially pronounced in *Luffa* (Figs. 8, 9).

Due to the enormous increase in size of the cellular part of the endosperm and the aggressiveness of the haustorium, the surrounding nucellar tissue is gradually used up.

The chalazal haustorium remains oocystic in *Trichosanthes*, *Luffa* and *Lagenaria*. Only in *Momordica* does it sometimes become cellular. It is at the peak of its activity at the heart-shaped stage of the pro-embryo, after which its contents begin to degenerate and disappear and the wall shrinks, and it comes to lie close to the base of the cellular endosperm (Fig. 8).

In advanced stages the endosperm is consumed by the developing embryo, and at maturity the cotyledons occupy the whole of the seed cavity.

Figs. 1-4. Development of endosperm in *Momordica charantia*; for explanation, see text. Fig. 4 is enlargement of the part marked N in Fig. 3. Magnification: Figs. 1 and 4, $\times 75$; Figs. 2, 3 and 5, $\times 10$.
Figs. 6 and 7. Endosperm of *Trichosanthes angurina*; Fig. 7 is enlargement of the part marked B in Fig. 6. Magnification: Fig. 6, $\times 24$; Fig. 7, $\times 110$.
Figs. 8 and 9. Endosperm of *Luffa acryptica*; Fig. 9 is enlargement of the part marked A in Fig. 8. Magnification: Fig. 8, $\times 11$; Fig. 9, $\times 112$.
Figs. 10 and 11. Endosperm of *Lagenaria vulgaris*; Fig. 11 is enlargement of the part marked J in Fig. 10. Magnification: Fig. 10, $\times 9$; Fig. 11, $\times 112$.

None of the families believed to be allied to the Cucurbitaceae is known to possess a similar endosperm oecum, but it would be interesting to reinvestigate them using whole mounts as well as sections.

I thank Prof. P. Maheshwari and Dr. B. M. Johri for their encouragement and valuable suggestions during the course of this study.

Plasmodium berghel in the Placenta of Mice and Rats: Transmission of Specific Immunity from Mother Rats to Litters

THE problem of transplacental transmission of *Plasmodium berghel* from mother mice and rats to their litter was investigated by infecting gravid animals during the week preceding parturition. 22 white mice and 12 albino rats were inoculated intravenously with a standard dose of 10^4 parasites per 100 gm. weight of the animal. All mice died

within an average of 12.4 days after the infection. Ten rats survived the infection and developed a consequent immunity. 15 mother mice lived long enough to deliver; two of which produced stillborn litters while 13 delivered normally. All live-born baby mice were free from infection at the time of birth, and when nursed by foster mothers remained healthy and developed normally for more than two months. The stillborn mice showed no parasites on direct smears, and sub-inoculations from them were negative; but they had an accumulation of pigment in the liver. This pigment (giving a negative histochemical test for iron) might have been produced as a result of a fatal intra-uterine infection.

Ten gravid rats infected with *P. berghel* showed a typical course of infection followed by recovery. They produced a total of 76 non-infected baby rats, all of which, nursed by their own mothers, developed normally for more than three months. Sections of placentae of three mother rats showed a heavy concentration of pigmented parasites in decidual sinuses and in the meshes of the placental

labyrinth; but the foetal villi were free from parasites. Neither the syncytial trophoblastic tissue nor the cellular elements of the placental labyrinth showed any marked reaction to parasites accumulated in the lacunae in very great numbers. The phagocytic activity of the 'giant cells' was not unduly marked, though some of them contained grains of pigment.

It seems that the penetration of parasites through the haemoendothelial barrier of the placenta of mice and rats is an exceptional occurrence, due perhaps to a mechanical or most probably functional deficiency, and followed as a rule by an early death of the foetus.

The transmission of specific immunity from mothers to their litter was investigated in rats. Ten adult females were given, after their recovery from

the first infection, three to four weekly intraperitoneal inoculations of *P. berghoi*, beginning with 20 million and ending with 60 million parasites. The rats were mated, and during the second half of their pregnancy received one or two intravenous inoculations of 25 million parasites.

All these rats produced normal litters which were nursed by their own mothers. Each litter was divided into three groups, and the combined litters in each group were challenged by an intraperitoneal inoculation of 1-3 million parasites at 2 weeks, 3 weeks and 4-5 weeks of age. The baby rats were followed up by blood examinations every two days (Table 1).

Table 1. RESULTS OF CHALLENGING INFECTIONS WITH *P. berghoi* OF LITTERS PRODUCED BY IMMUNE AND NORMAL MOTHER RATS

	Litter from immune mothers			Litter from normal mothers		
	Age at challenge (days)			Age at challenge (days)		
	13-15	20-22	23-25	13-15	21-23	23-24
Numbers challenged	22	20	18	18	19	20
Dose of parasites	10 ¹	2 × 10 ¹	3 × 10 ¹	10 ¹	2 × 10 ¹	3 × 10 ¹
Numbers died	22	17	9	18	19	19
Mortality (per cent)	100	85	50	100	100	94.5
Average survival time of fatal infections (days)	12.5	15	18.6	10.8	14.6	14.8
Mean peak parasitaemia (per cent parasitized red blood cells)	94.0	80.5	67.4	94.4	98.5	91.0

It appears that young rats born from mothers immune to *P. berghoi* exhibit some tolerance to a challenging infection with this parasite, whereas the infection in control baby rats delivered from normal mothers is usually fatal. This transmitted tolerance becomes obvious only towards the end of the nursing period.

To find whether the young rats obtain their inherited relative immunity through milk, four groups of litters produced by two immune and two normal mother rats were interchanged at the age of 3-4 days after birth and later challenged at the age of 15 and 30 days respectively (Table 2).

Table 2. RESULTS OF CHALLENGING INFECTIONS WITH *P. berghoi* IN TWO GROUPS OF INTERCHANGED LITTERS

	Litter from immune mother nursed by a normal mother		Litter from a normal mother nursed by an immune mother	
	Age at challenge (days)		Age at challenge (days)	
	15-16	30-32	14-16	31-32
Numbers challenged	6	7	7	8
Numbers died	6	6	6	5
Mortality (per cent)	100	85	85	62.5
Average survival time of fatal infections (days)	14.5	16	12.2	13.5
Mean peak parasitaemia	91.0	94.6	93.7	76.0

The results of this preliminary investigation suggest that any inherited relative immunity to challenging infections with *P. berghoi* in young rats is transmitted mainly by milk of immune mothers and evident only during the late part of the nursing period.

Spawning Sites of Trout

In a previous communication¹, it was stated that field observations suggest there is a regular downward flow of water through the gravel beneath the river-bed at the sites favoured by salmon and trout when making the spawning redd. The course of these sub-surface currents, as experimentally determined in the laboratory in a 6 ft. × 1 ft. artificial stream pool, was described. It was found that the maximum flow occurs in the vicinity of the mound of gravel usually present near the lower end of a spawning pool, that is, where redds are commonly found. The present spawning season offered an opportunity of testing the behaviour of a pair of gravid trout introduced into the experimental pool. Normal 'courtship' behaviour was observed and spawning took place. Ova (425) were deposited in three pockets, all excavated within the predicted area, the site of the initial cutting being just below the apex of the gravel mound, where the strongest sub-surface flow had been found to occur; 100 per cent fertilization resulted. In a second experiment with another gravid pair, three pockets of ova have been again deposited in exactly the same site.

An interesting demonstration of the penetration of stream water into the sub-surface gravel was obtained by burying ripe ova, obtained by stripping a female trout, in the mound of gravel in the experimental tank, some 4 ft. distant from the inflow. A dilute suspension of spermatozoa from a ripe male was then poured into the inflow rush. Investigation showed 30 per cent of the buried ova to have been fertilized by spermatozoa carried by downward currents through the gravel. A second similar experiment with a more concentrated suspension of spermatozoa yielded just over 60 per cent fertilization. These results suggest that in a stream with a mixed salmonid population cross-fertilization is at least possible on physical grounds.

A New Species of Freshwater Triclad belonging to the Genus *Polycelis*

OUR studies of the genus *Polycelis* from western Europe have revealed that the species complex *nigra-tensis* in reality includes not two but three different species, which are easily recognized if the anatomy of the copulatory organs or the chromosomes are studied. However, it is scarcely possible to identify these species from their external appearance.

Below, the main species differences are set down, though the anatomy (E. H.-M.) and the chromosomal conditions (Y. M.) will be described soon, in full, elsewhere.

Polycelis nigra (O. F. Müller, 1773) has a short, rounded penis with two to three rows of chitinous spines around its opening. The glandular bursa is large. There are no adenodactyls.

Polycelis tenuis Ijima, 1784 has a large, long and pointed penis, the surface of which is covered with thick chitinous spines. The glandular bursa is a small one. This species always has two well-developed adenodactyls.

Polycelis hepta n.sp. will be the name of the new species formerly confused with the other two. It has a large pointed penis like that of *tenuis*. The distal third of the surface of the penis is covered with small epithelial light-refracting bodies. The glandular bursa is similar to that of *tenuis*. There are never any adenodactyls in *hepta*.

The haploid chromosome number is 8 in *nigra*, 8 in *tenuis* and 7 in *hepta*. The name of the latter species refers to the chromosome number. *Nigra* is commonly diploid, whereas *tenuis* has established a bisexually reproducing tetraploid form in England. Out of the diploid *hepta* have arisen triploids and tetraploids with $3 \times 7 = 21$, and $4 \times 7 = 28$ chromosomes respectively. These latter forms are able to propagate either by obligate or facultative parthenogenesis. The polyploid parthenogenetic forms are very successful, having a distribution over most parts of western Europe, whereas the bisexually reproducing diploid type, according to our knowledge, is restricted to a few localities in the mountains of western Europe.

Some observations have been made on the ecology of *P. hepta* during a survey of the triads of lakes (T.B.R.). Other kinds of freshwater habitats are not dealt with here.

The most oligotrophic British lakes do not support a *Polycelis* fauna. *Nigra* is the first species to appear in the less oligotrophic lakes. In lakes of increasing eutrophy it is gradually replaced by the tetraploid *tenuis*, which becomes numerically dominant. *Polycelis hepta* occupies a position of relative maximum abundance in lakes between the two extremes, but extending into the eutrophic habitat. It is therefore found with both *nigra* and *tenuis* but more usually with the latter, and mixed populations of *tenuis* and *hepta* are the rule. However, in certain lakes not rich enough to support *tenuis*, *hepta* may occur with *nigra*, less commonly alone. In Sweden, *Polycelis hepta* is similarly related to *tenuis* ecologically; but some differences may be attributed to the fact that the latter species is diploid in Sweden and not tetraploid as in the British lakes. Another contrast between the two areas which has ecological consequences is the lack of competition from *Polycelis nigra*, which does not occur in Swedish lakes.

Breeding of Mice at -3°C .

THE house mouse, *Mus musculus* L., can live and breed¹ in cold stores kept permanently well below 0°C . We have found that laboratory strains of this species, provided with cotton wool for nesting, can be bred in cages in a room kept at -2° to -4°C .

Two families of white mice, of the Strong A strain, have, in nine and ten months respectively, reached the third generation born and reared in the cold. Control families, derived from litter mates of the experimental mice, were kept at 10° and 20°C . respectively: these reached the fourth generation in the same time. One family of inbred O67 (black) mice has, in eight months, reached the second

generation in the cold; in the same time, a control family reached the third generation at 20°C . We find no reason for doubting that these two strains could be bred indefinitely at -3°C .

The fertility of mice reared at 20°C , and transferred to -3°C . before mating, has been compared with that of litter-mate controls kept at 20°C . Ten pairs of the Strong A strain were mated at each temperature, and bred for periods of 18-27 weeks, with the following results:

	-3°C .	20°C .
No. of litters born	42	48
No. of litters weaned	37	44
Total young weaned	176	231
Mean number young weaned per weaned litter	4.73 S.D. -1.66	5.25 S.D. -1.66
Mean weight in gm. at weaning	8.70 S.D. -1.61 9.02 S.D. -2.11	10.10 S.D. -1.76 10.46 S.D. -1.66

Temperatures in the nests, of pairs with litters aged 1-7 days, were recorded by means of a thermocouple put on or among the nestlings. In the cold room the nest temperatures varied from 20.2° to 32°C . in twenty readings; eleven of the readings were higher than 26°C . Pairs with older, more active litters, or without litters, did not maintain nests at such high temperatures. In the room kept at 20°C . the temperatures of nests with young litters varied from 27.8° to 30.8°C . in eight readings. Nests in the cold were better constructed than those in the warm.

The general conclusion is that, in the conditions of this experiment, laboratory mice are able to make a physiological adaptation to temperatures below freezing point, without major loss of fertility. The functional changes involved in this process are being studied.

The work is aided by a grant from the Nuffield Foundation.

Occurrence of the Lancelet in Haifa Bay, Israel

A SPECIMEN of *Branchiostoma lanceolatum* (Pallas) was collected during the September 1953 cruise of the research vessel of the Sea Fisheries Research Station at a position at $32^{\circ} 53' 36''\text{N}$, $35^{\circ} 1'\text{E}$, in Haifa Bay at the depth of 15 fathoms. Another station in the eastern Mediterranean has thus been added to the zoogeographical distribution of the lancelet. It was not unexpected that the animal should occur somewhere along the Israel Mediterranean coast, in view of the geographical proximity of the other stations where the species has been previously recorded. The lancelet, however, was not found during the previous bottom investigations carried out along the Israel coast during the years 1946-52 at the 10-, 30-, 50- and 75-fathom lines, of which only the 10-fathom line lies on sandy bottom. In these investigations a Pettersson bottom-grab and a dredge were used.

At the station where the specimen was collected, the bottom is composed of gravel in which mollusc shells, bryozoan skeletons and corals are found, and it is in the vicinity of a sandy area interposed by rocks.

Of the thirteen species of the genus *Branchiostoma*, *B. lanceolatum* is the only one to be found in the Mediterranean. Steuer² collected specimens of the lancelet in the vicinity of Alexandria (September–November 1933); their maximal size was 32 mm. and they conformed with *forma typica*. He further mentions that those collected off Rovigno d'Istria (September 1935) were of 43.5 mm. maximal size, and states that a different specific form of this species occurs in the Black Sea.

The specimen collected in Haifa Bay measures 36 mm., weighs 0.127 gm., has 59 myotomes and seems to conform with the typical form of the species *Branchiostoma lanceolatum* (Pallas).

ABO Groups in Blood Platelets

It has been found that suspensions of blood platelets in normal saline are agglutinated by A-, B- and O-sera, just as these sera agglutinate red blood cells of the corresponding blood group. It is thus possible to establish four blood groups for the blood platelets, similar to the blood groups in erythrocytes.

The following technique was used in the study. All glassware was coated with silicone to render it non-wettable. Disodium sequestrene was used as an anticoagulant. Triton W.R. 1339¹ 2 per cent¹ was added to reduce irreversible clumping of the thrombocytes. Blood freshly drawn into siliconized tubes was centrifuged in cups filled with ice, at 800 r.p.m. for ten minutes. The plasma was pipetted off and centrifuged again for five minutes at 800 r.p.m. in order to remove the remaining red and white blood cells.

Plasma containing a pure suspension of thrombocytes was now centrifuged five minutes at 2,000 r.p.m. to obtain a sediment of concentrated blood platelets. The plasma was then siphoned off, and it was found that the sediment contained a concentration of 3–5 million platelets per cubic millimetre. This sediment was washed three times with normal saline and then suspended in normal saline at a dilution of 1:10, in order to obtain a count of about 500,000 per c.mm.

The typing of the blood platelet suspension was performed as follows. To 0.3–0.5 c.c. of inactivated serum in a tube an equal volume of the platelet suspension was added and left at room temperature for two hours. The result of agglutination was read microscopically after two hours, by withdrawing several drops of the serum-platelet suspension and spreading it on a slide. Agglutinates of different sizes, from several to tens of thrombocytes, and large clumps of platelets were clearly visible at low magnification. At the first reading after two hours, about 30 per cent of the platelets remained unagglutinated. When left at room temperature for eight hours, large clumps of agglutinated thrombocytes were seen macroscopically. Control examinations of platelets

suspended in their own serum or in inactivated serum of the same group always remained negative. No signs of agglutination in the control tests were observed after 24 hr. Similar results were obtained at both 37° C. and at room temperature.

Examinations of platelets from forty different bloods have been carried out, and all have corresponded to the erythrocyte grouping.

When fresh non-inactivated sera were used, or when fresh complement was added to the inactivated serum, a mesh was formed which contained the thrombocytes.

Platelets from blood of group	A serum	B serum	O serum	AB serum	0.9 per cent sodium chloride
O	—	—	—	—	—
A	—	+	+	—	—
B	+	—	+	—	—
AB	+	+	+	—	—

+, Agglutination; —, non-agglutination.

The accompanying table illustrates agglutination of blood platelets by A-, B-, O- and AB-sera.

Hypoglycin A,B: Biologically Active Polypeptides from *Blighia sapida*

THERE is evidence in literature dating from 1887¹⁻³ that the fruit of *Blighia sapida* (known in Jamaica as *ackee* and in Nigeria as *irin*), a very common article of diet in Jamaica, may contain toxic components. Also, it has been suggested that these components are a contributing cause of Jamaican 'vomiting sickness', an important local disease of, as yet, undefined etiology⁴⁻⁶. However, this view has not been generally accepted^{7,8}. We have attempted the isolation and study of the toxic constituents of the fruit in order to examine the hypothesis.

We have found that the seed of the fruit contains two toxic polypeptides which we have named hypoglycin A and hypoglycin B. The ripe arillus, which is the common article of diet, contains a small concentration of hypoglycin A only. The unripe arillus contains a higher concentration of this compound.

The isolation of the active constituents was controlled by toxicity tests using kittens, rats and guinea pigs. At the outset these tests confirmed earlier observations that the toxicity was extracted by water^{3,4,6}. The active components were separated from water-soluble plant pigments, acids, sugars and starch by absorption on a sulphonated ion-exchange resin. The crude material obtained on elution contained the toxic constituents mixed with some fifteen amino-acids. This mixture was separated quantitatively on ion exchange columns, the procedure being controlled by paper chromatography in addition to toxicity tests. The final purification of hypoglycin A and B was achieved by chromatography on powdered cellulose columns and recrystallization.

Hypoglycin A (melting point 280–284°; $[\alpha]_D^{20}$, +6.75° ± 4° (water): C, 59.40; H, 8.12; N, 11.2

per cent) is a neutral compound which crystallizes readily from methanol-water. It gives a blue ninhydrin reaction and is hydrolysed by hydrochloric acid to a mixture of amino-acids. Paper chromatography using butanol-acetic acid-water (8:1:8) and phenol-water (25 per cent)-ammonia (0.5 per cent) gives single spots with R_F values 0.60 and 0.83 respectively. The infra-red absorption spectrum is in agreement with its formulation as a polypeptide.

Hypoglycin B (double melting point, 194-195°; 200-208°; $[\alpha]_D^{25} + 9.65 \pm 2^\circ$ (water); C, 52.87; H, 6.88; N, 10.55 per cent) is an acidic compound which crystallizes from water-acetone. It gives a blue ninhydrin reaction and is hydrolysed by hydrochloric acid. Paper chromatography using butanol-acetic acid-water (8:1:8) and phenol-water (25 per cent)-ammonia (0.5 per cent) gives spots of R_F value 0.61 and 0.60 respectively.

Both compounds were lethal to kittens, guinea pigs and rats. An estimation of LD₅₀ using twenty-four adult albino rats (body-weight 150-225 gm.) at four dose-levels gave a value of approximately 90 mgm./kgm. for hypoglycin A, but the toxicity was more than doubled when fasted animals were used. Hypoglycin B was approximately half as toxic as hypoglycin A. Hypoglycaemic activity was the most striking pharmacological property observed. Blood glucose invariably fell to less than 20 mgm. per cent before death. There was no significant change in the levels of plasma cholesterol or chloride ion, although the concentration of plasma urea increased to approximately twice normal before death. Histological evidence indicated a marked reduction in the concentration of liver glycogen.

Recently, a study on nine cases of Jamaican vomiting sickness demonstrated that in all instances there was severe hypoglycaemia (3-22 mgm. per cent blood sugar). It was considered that the clinical evidence indicated that the condition was induced by ingested toxic substances*. These observations, and the fact that natural products giving rise to marked hypoglycaemia and low liver glycogen are of limited occurrence, provide further circumstantial evidence of a connexion between the fruit of *Blighia sapida* and vomiting sickness.

Details of this work and further chemical investigations on hypoglycin A and B will be published elsewhere. We are indebted to Mr. Bryan Lutz-Wallace for technical assistance and gratefully acknowledge a grant from the Government of Jamaica.

Genic Equilibrium of Microcythemia in some Italian Districts

MICROCYTHAEMIA, or thalassaemia minor, is an inherited trait due to an autosomal gene (M), with incomplete dominance, which in the homozygous condition is lethal because all MM die in childhood from a severe anaemia (Cooley's disease or thalassaemia major). Silvestroni *et al.*¹ showed that its frequency ranges, in Italy, from 0.47 per cent (Florence) up to 10.4 per cent (average of several villages in the district of Ferrara), with a rather irregular distribution through the Italian peninsula and islands. They pointed out that the high percentage of microcythemia (Mm) in some populations raises the problem of how such a high percentage of heterozygotes can be preserved through many generations although the gene M is continually eliminated because all homozygotes (MM) die in early childhood.

From the data collected at that time it appeared that the phenomenon could be explained mainly by the fact that $Mm \times Mm$ matings seemed to be more fertile than the others (see Table 2, ref. 1). Haldane (personal communication) has shown that this increase in fertility is insufficient to maintain equilibrium: if the frequencies of Mm and mm are in the ratio $X_n : (1 - X_n)$ in the n^{th} generation, and $Mm \times Mm$ matings produce f times as many children as other types, then, in the next generation:

$$X_{n+1} = (X_n - X_n^2 + \frac{1}{2}fX_n^2)/(1 - X_n^2 + \frac{1}{2}fX_n^2).$$

For equilibrium, $X_{n+1} = X_n = (4 - 2f)/(4 - 3f)$: since $0 < X < 1$, $f > 0$; this implies that $f > 2$, which was not the case in the above data.

Further and more extensive data collected in the summer of 1951 by Silvestroni *et al.*² showed that the percentage of Mm was even higher in some localities near the region of the Po delta (nearly 20 per cent), but in the larger sample thus available, $Mm \times Mm$ matings no longer showed increased fertility (Table 1; the families used in this case were those in which the mother was more than forty years of age, to ensure that all families were complete). Thus, the hypothesis of a differential fertility in favour of one particular type of mating is no longer tenable.

Table 1. DATA COLLECTED IN 1951 (see ref. 3)

Type of mating	Number of families	Average number of children per family	S.E.
$mm \times mm$	1,286	4.89	0.183
$Mm \times mm$	793	5.03	0.217
$Mm \times Mm$	79	4.99	0.749

Another possible explanation is increased fitness of the genotype Mm . In this case it is easy to demonstrate that even a very small advantage could be enough to keep the genic system in equilibrium⁴.

Penrose⁵ showed that, when there is equilibrium, fitnesses may be expressed in terms of gene frequencies. Denoting by q and p the respective frequencies of the normal gene m and the mutant gene M , we have $f = 1 - kp^2$, $g = 1 + kqp$, $h = 1 - kq^2$, as the fitnesses of mm , Mm , MM , respectively, where k is a constant.

Since we know that the fitness of MM is zero (because these individuals die before the age of reproduction), we obtain from the last relation the actual value of k as 1.108, and therefore the theoretical values of f and g for equilibrium are:

$$f = 1 - kp^2 = 0.997 \\ g = 1 + kqp = 1.053.$$

This means that a difference of the order of 0.05 could be enough to balance the loss of the gene *M*.

In practice, it is difficult to measure 'fitness'. A direct measure is given by the ratio of the proportion of a genotype among parents to that among offspring (Penrose⁴). In this way, we obtained a rough estimate of the actual values of fitnesses in our populations (Table 2).

Table 2

Genotype	Frequency among 5,904 parents (a) (per cent)	Frequency among 10,355 offspring (b) (per cent)	Direct estimate of fitness (a/b)	Theoretical value for equilibrium
<i>mm</i>	89.9	89.5	1.004	0.997
<i>Mm</i>	10.1	9.8	1.031	1.053
<i>MM</i>	0.0	0.7	0.000	0.000

From this table it may be seen that, although it is not possible to demonstrate the significance of the difference in the fitness values between the two genotypes *Mm* and *mm*, this difference is in the right direction and of the right order of magnitude.

Formation of Nitrite from Oximes and Hydroxylamine by Micro-organisms

It has recently been shown¹ that a number of micro-organisms can form nitrite from various oximes, although the mechanisms involved have not yet been elucidated. We have now established that some organisms capable of forming nitrite from oximes (for example, *Alcaligenes*, *Corynebacterium equi*, and strains of *Nocardia coralina*) can also form nitrite from hydroxylamine if the hydroxylamine is added in sufficiently low concentrations to washed suspensions of the cells. Typical results are shown in Table 1. Nitrite formation from both hydroxylamine and pyruvic oxime was inhibited by hydrazine over the range *M*/100–*M*/1,000 hydrazine, but not by *M*/1,000 thiourea or allylthiourea.

These results suggest that both hydroxylamine and pyruvic oxime may be converted to nitrite in these organisms by a similar path. They also suggest that this path may resemble that involved in the formation of nitrite from hydroxylamine in *Nitrosomonas*, where a mechanism of formation sensitive to hydrazine but insensitive to thiourea or allylthiourea is also known to occur². Further details about this mechanism are not, however, available, simply because

Table 1. THE FORMATION OF NITRITE BY WASHED SUSPENSIONS OF *Nocardia coralina* (STRAIN K 6). Cells washed with, and suspended in, *M*/30 phosphate buffer, pH 6.5. Final volume, including all additions, 5 ml. Incubated for 2 hours at 25° with constant shaking. Cell density, 10 mgm. per ml. (approx.)

* Boiled cell suspension.

Nitrosomonas is so difficult to culture in adequate quantity.

Heterotrophic oxime-oxidizing organisms are, on the contrary, very easily cultured. We therefore intend to study the mechanisms whereby these organisms oxidize hydroxylamine to nitrite. We hope these studies will shed some light on the mechanism of the same process as carried out by the autotrophic *Nitrosomonas*.

Electrophoretic Behaviour of Hyaluronidase

WHILE the role of hyaluronidase seems to be understood from the biological point of view, there is little information about the constitution and chemical properties of this enzyme; this is due, indeed, to the great difficulty in preparing and purifying the enzymic fraction from the 'mucopolysaccharase complex'. Even in the Hahn¹ procedure, which gives highly active preparations, the so-called purified material is not at all homogeneous as judged by its behaviour in the electrophoresis apparatus and in the ultracentrifuge.

The present communication describes preliminary results of the fractionation of hyaluronidase preparations by filter-paper electrophoresis, in view of the special advantages of filter-paper electrophoresis for studying the enzymic properties of some proteins.

The technique was essentially that of Durrum², using bromophenol blue as stain. The hyaluronidase used for this investigation was prepared from bull testicles by the method of Favilli and Bergamini³; in some experiments, Vister hyaluronidase ('Jalovis', for which I am indebted to Prof. Soldi, of the Vister Laboratories) was employed. In the electrophoretic pattern of the hyaluronidase preparations, four distinct components with different mobilities were observed; in order to determine which of the four components was enzymically active, the portion of the paper strip containing each component was cut out after a run, eluted by the same buffer, and tested for hyaluronidase activity by the turbidimetric technique⁴. Before eluting from the paper strip, a thin

strip on the side was stained to determine the exact position of each component. All the hyaluronidase activity was found to be in the slowest component (Fig. 1). At pH 8.0, therefore, excellent separation of the enzymically active component from the other fast-moving fractions was obtained, which suggests that this technique can be usefully employed in the purification of hyaluronidase. It is also of interest that the mobility of the fastest component was actually greater than that of the albumin.

In order that the real mobility of each component and the isoelectric point of the enzymically active component might be calculated, some experiments were carried out with the classical Tiselius electrophoresis method, using the Perkin-Elmer apparatus. As shown in Fig. 2, the diagrams are almost the same as that obtained with paper electrophoresis; there are, however, slight differences in the mobilities of the intermediate components. From the calculations based on the pH-mobility curve (Fig. 3) the isoelectric point of the enzymic component falls at pH 5.75. This is in agreement with the value found by Hahn.

It seems, in the light of these observations, that the paper-electrophoresis method is, at present, the best procedure for separating the enzymic fraction from the impurities of hyaluronidase preparations.

A fuller discussion of these results will appear elsewhere.

Non-participation of Folic Acid in the Biosynthesis of Methyl Compounds from Precursors

THE observed impairment in normal creatine and nicotinamide metabolism in folic-acid deficiency, and its partial restoration by administered methanol or formate¹, suggest that a function of folic acid is to check the drain of methyl compounds to formate. The possibility that folic acid may also catalyse the synthesis of methyl compounds from precursors has now been examined.

Adult mice (inbred Swiss strain) were rendered deficient in folic acid as before and divided into groups of four (see table), receiving as supplements folic acid (10 γ/mouse/day, orally) and/or methanol (1 mgm./mouse/day, intraperitoneally) with corresponding controls. On the eighth night from the commencement of this grouping, feed cups were withdrawn from all the cages; on the following morning animals of groups 2 and 4 were each given intraperitoneally 0.6 c.c. of a solution containing 1 mgm. of methanol and 2 mgm. of *DL*-serine; stoichiometrically, these additions represented an approximate molecular ratio of 3:2, since one mole of *L*-serine gives rise to one of ethanolamine through decarboxylation, *D*-serine being inactive in this respect². It should be stated that even though

Group	Choline (mgm./gm. of liver)	Methionine (mgm./gm. of liver)	Phospho- creatine (mgm./gm. of muscle)
1. Basal (no folic acid)	5.17 ± 0.07*	4.80 ± 0.56*	0.337 ± 0.026*
2. Basal + methanol + serine	5.50 ± 0.10	5.23 ± 0.14	0.355 ± 0.034
3. Basal + folic acid	6.07 ± 0.02	5.04 ± 0.09	0.457 ± 0.043
4. Basal + folic acid + methanol + serine	6.35 ± 0.48	5.76 ± 0.83	0.415 ± nil

* Standard error.

serine could be derived *in vivo* from methanol, it was administered simultaneously here to eliminate the known effect of folic acid at this step. Animals in groups 1 and 3 were given mock injections with similar quantities of distilled water. All animals were allowed access to food one hour after injection. They were sacrificed five hours later; liver, viscera and samples of skeletal muscle were quickly removed and stored in a deep freeze ($-5^{\circ}\text{C}.$) for determinations of choline³ and methionine⁴ in the former and of phosphocreatine⁵ in the latter.

The observed increase in the values for choline, methionine and phosphocreatine in group 3 over those in group 1 may be due to a greater conservation of labile methyl due to the check on its breakdown to formate³ as well as to possible increased biogenesis from metabolically derived precursors. However, if the latter were the case, it was to be expected that exogenously supplied precursors should be better utilized for methyl synthesis in presence of folic acid (group 4) than in its absence (group 2). This is not substantiated by a comparison of the data for these groups with the corresponding figures for the control groups.

Density of Visual Pigment in the Frog Retina

A METHOD for preparing suspensions of the frog visual end-organs which were suitable for spectrophotometric analysis¹ has been used to redetermine the density of visual purple in the frog's retina.

Retinae were removed from the eyes of dark-adapted frogs, using a method described by Lythgoe in 1937. The period of dark-adaptation was 12 hours or more. The retinae were washed in frog Ringer-Locke solution, shaken in 35 per cent w/v sucrose solution, and centrifuged. The outer limbs of the rods and cones floated undamaged in the sucrose, while the other cells of the retina were spun down. Details of each preparation are given in Table 1. The sucrose suspension of the end-organs was put into absorption cells the path-length of which was 5.0 mm. The change in the optical density of the suspension when it was exposed to light was measured at wavelengths 495, 505, 515 and 525 m μ . The maximum of the difference spectrum of the visual pigment contained in the cells of the suspension was found by interpolation of these results.

Table 1
